ESSA TECHNICAL MEMORANDA

Weather Bureau, Techniques Development Laboratory Series

The primary purpose of the Techniques Development Laboratory of the Office of Systems Development is to translate increases in basic knowledge in meteorology and allied disciplines into improved operating techniques and procedures. To achieve this goal, TDL conducts and sponsors applied research and development aimed at improvement of diagnostic and prognostic methods for producing weather information. The laboratory carries out studies both for the general improvement of prediction methodology used in the National Meteorological Service System and for more effective utilization of weather forecasts by the ultimate user.

ESSA Technical Memoranda in the Weather Bureau Techniques Development Laboratory series facilitate rapid distribution of material which may be preliminary in nature and which may be published formally elsewhere at a later date. The first five papers in the TDL series are part of the former Weather Bureau Technical Notes series.

Papers listed below are available from the Clearinghouse for Federal Scientific and Technical Information, U.S. Department of Commerce, Sills Bldg., 5285 Port Royal Road, Springfield, Va. 22151. Price: $3.00 hard copy; $0.65 microfiche. Order by accession number shown in parentheses at end of each entry.

TN 10 TDL 1 Objective Prediction of Daily Surface Temperature. William H. Klein, Curtis W. Crockett, and Carlos R. Dunn, October 1965. (PB-168 590)

TN 11 TDL 2 Hurricane Cindy Galveston Bay Tides. N. A. Pore, A. T. Angelo, and J. G. Taylor, September 1965. (PB-168 608)

TN 29 TDL 3 Atmospheric Effects on Re-Entry Vehicle Dispersions. Karl R. Johannessen, December 1965. (PB-169 381)

TN 45 TDL 4 A Synoptic Climatology of Winter Precipitation from 700-mb. Lows for the Intermountain Areas of the West. D. L. Jorgensen, W. H. Klein, and A. F. Korte, May 1966. (PB-170 635)

TN 47 TDL 5 Hemispheric Specification of Sea Level Pressure from Numerical 700-mb. Height Forecasts. William H. Klein and Billy M. Lewis, June 1966. (PB-173 091)

WBTM TDL 6 A Fortran Program for the Calculation of Hourly Values of Astronomical Tide and Time and Height of High and Low Water. N. A. Pore and R. A. Cummings, January 1967. (PB-174 660)

WBTM TDL 7 Numerical Experiments Leading to the Design of Optimum Global Meteorological Networks. M. A. Alaka and F. Lewis, February 1967. (PB-174 497)

PERSISTENCE OF PRECIPITATION AT 108 CITIES IN THE CONTERMINOUS UNITED STATES

Donald L. Jorgensen and William H. Klein

ABSTRACT

Values of persistence of precipitation for each of the four seasons have been derived for 108 cities in the conterminous United States for a selected combination of time intervals. These values show significant differences between stations and seasons and shed considerable light on the general behavior of storm systems and atmospheric circulations responsible for precipitation occurrences. Examples are given illustrating the application of persistence to the forecasting problem, and the relationship between persistence and the coefficient of correlation involving successive precipitation events is developed. The data presented should serve as important supplementary information to the forecaster in evaluating continuity trends in precipitation.

INTRODUCTION

In earlier studies, precipitation data for a network of reporting stations in the 48 conterminous states were used to provide climatological probabilities of precipitation occurrence [7] and conditional probabilities of receiving specified amounts [9]. In the first study, probabilities (climatological relative frequencies) were derived for several time periods making up and including the 24-hour period. Data were presented as monthly averages for each of the 12 months. In the second study, these data were grouped into four seasons, and probabilities of receiving cumulative amounts in seven ranges were derived on the condition that precipitation would occur. For comparative purposes, unconditional climatological probabilities were also included.

In addition to climatological characteristics of precipitation represented by these two studies, knowledge of a third characteristic is of considerable interest to the meteorologist in evaluating storm behavior. This is the manner in which precipitation tends to persist. Persistence of precipitation reflects the dimension and movement of the atmospheric circulation responsible for that precipitation. For small-scale phenomena such as air-mass thunderstorms, precipitation may be of short duration, while for large-scale cyclonic systems it may continue for much longer periods. In a still broader sense, continuation or persistent recurrence of precipitation may be closely associated with circulation patterns consisting of long waves in the atmosphere. When a large-scale ridge-trough system becomes stationary over a geographic region, a prolonged wet spell may be experienced just east of the trough and a drought in the vicinity of the ridge [10]. Average persistence at a particular location then depends on the frequency, intensity, location of storms of varying dimensions, and on the average rate

of movement of long waves through the area.

Various studies [e.g., 1, 2, 8, 11] have been made on persistence of precipitation. In each instance, a single station or a restricted region was investigated, and a variety of time periods and definitions of persistence was employed. As a result, a clear picture of the way in which persistence varies with season and geographical area has not yet been established. A theoretical treatment of persistence may be made through the use of the Markov chain [3, 6, 14] and other [5] models, but these approaches are not used in the current investigation. A recent study [12] presents an empirical method for expressing the recurrence of weather events exhibiting strong diurnal effects.

It is the purpose of this report to examine persistence of precipitation for rather limited time sequences for a broad geographical area and for varying seasons. This objective is achieved by means of an empirical examination of precipitation data. Of additional interest is the manner in which persistence is related to the coefficient of correlation between precipitation occurrence in preceding and following periods. This relationship is discussed briefly in Appendix A.

The data on which this report is based are the same as those used in our earlier studies [7, 9]. They consist of a compilation for 108 cities of 15 years of precipitation records, September 1949 through August 1964, which were accumulated by the National Weather Records Center, Asheville, N. C., for the Techniques Development Laboratory. These data were then processed to give the persistence of occurrence of precipitation for selected time periods.

PROCEDURE

Occurrence of precipitation is a discontinous function. This characteristic requires that persistence be treated in two parts: (1) those cases where the previous period was wet, and (2) those cases where the previous period was dry. In this sense, persistence can be considered as a conditional probability with the condition being the occurrence or nonoccurrence of precipitation in the preceding period. The two types of persistence are then defined as the probability of occurrence of precipitation in the verifying period following the wet cases, P_W, (wet persistence) and following the dry cases, P_D, (dry persistence)[1]. Since the probabilities expressing the persistence of occurrence and nonoccurrence must add to unity, the probability of nonoccurrence is known once the probability of occurrence has been determined.

---

1. The term "dry persistence" is used for convenience of expression in the following discussions. It is not to be confused with persistence of dry weather, which is the complement of the values of dry persistence given here.

Persistence considered in the above sense will depend upon the definition of the "occurrence of the event" and upon the time intervals involved. In evaluating persistence of precipitation, various threshold amounts may be specified and various time intervals used. In this investigation, measurable amounts (0.01 inch or more) occurring within the given time periods represent an occurrence, while a trace or none constitute a nonoccurrence. To consider various characteristics of persistence, time intervals varying from 6 to 24 hours have been used in combination to define the prior period (the conditional period) and singly to define the verifying period.

In addition, data have been generated with a lapse of 6 hours between the conditional and verifying periods. This allows the forecaster to make use of the data without knowing the weather between the time the forecast is completed and the beginning of the forecast period. If these statistics were not available, the forecaster would have to predict the weather expected during the intervening period in order to make full use of persistence.

The conditional periods employed in this study consisted of 6-, 12-, and 24-hour time intervals. These periods have been grouped into three different combinations as follows:

Type A. - Single Periods (Periods wet or dry)

6 hours preceding verification period
12 hours preceding verification period
24 hours preceding verification period

Type B. - Two Combined Periods (Both wet or both dry)

6 plus 6 hours preceding verification period
12 plus 12 hours preceding verification period
24 plus 24 hours preceding verification period

Type C. - Single Periods With Time Lapse (Periods wet or dry)

6 hours ending 6 hours before verification period
12 hours ending 6 hours before verification period
24 hours ending 6 hours before verification period

The conditional periods given above are independent of time of day, but in each case they precede the verifying period by the indicated time interval. In order to evaluate diurnal effects of persistence, verifying periods were chosen as follows:

6-hour periods	12-hour periods	24-hour periods
00 - 06Z	00 - 12Z	00 - 24Z
06 - 12Z	12 - 24Z	12 - 12Z
12 - 18Z		
18 - 24Z		

Thus all statistics in this study are based on Greenwich Meridian Time (Z), rather than local time.

Combinations of conditional and verifying periods for the three types are shown graphically in figure 1, where zero time indicates the beginning of the verifying period without regard to time of day. For ease of interpreting tabular data, coded values associated with the three types are given in the right-hand column.

Precipitation data for each of the 108 cities and for each season were examined by computer to derive the relative frequency of occurrence of precipitation for each of the verifying periods as a function of the occurrence or nonoccurrence of precipitation during relevant prior periods. The resulting persistence probabilities are listed on computer printouts in tabular form in Appendix B.

The first two columns in the table in the appendix give persistence probabilities for individual cities when the 6-hour conditional period is dry and wet (D_1 and W_1) for each of the eight verifying intervals consisting of four 6-hour, two 12-hour, and two 24-hour periods. The second two columns (D_2 and W_2) give similar data for a 12-hour conditional period, and the third pair of columns (D_3 and W_3) give data for the 24-hour conditional period (all Type A combinations).

The next three pairs of columns give similar data for Type B combinations of periods. In this type, the conditional periods are made up of combined periods consisting of two 6-hour, two 12-hour, and two 24-hour intervals, both of which are either dry (D_4, D_5, and D_6) or wet (W_4, W_5, and W_6). Again the persistence is derived for each of the eight verifying periods.

The final six columns give data similar to those for Type A combinations, except that conditional periods are separated from verifying periods by a 6-hour interval. Precipitation occurrence or nonoccurrence during the intervening 6 hours is not considered in evaluating persistence of this type.

INTERPRETATION OF RESULTS

In considering the results of the investigation, background information on the general relationships between the basic data and persistence will first be presented. This will be followed by a discussion of the observed variability in the derived data. Finally, examples will be given to illustrate geographical and seasonal variations in persistence.

Background - As indicated in the previous section, derivation of persistence from observed data requires separation of cases into dry and wet classes. This separation is made on the basis of whether or not precipitation occurs in the conditional period. Consequently, the number of cases in the dry class will be proportional to the relative frequency of the nonoccurrence cases in the conditional period, and the number in the wet class will be

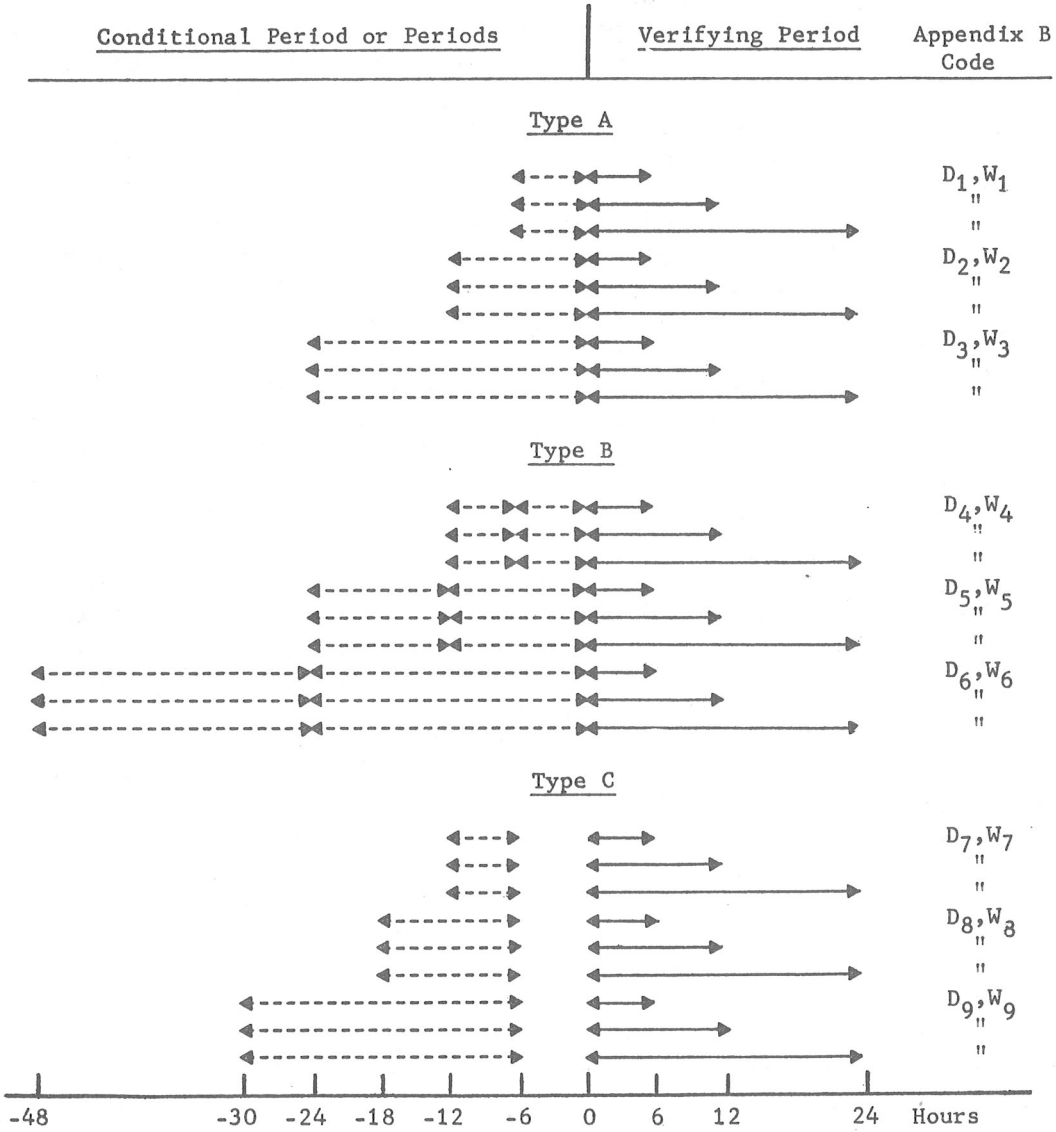

Figure 1. - Schematic representation of combinations of conditional (dashed) and verifying (solid) periods. The right-hand column indicates combinations of periods used in Appendix B, with "D" specifying dry and "W" wet conditions in the conditional periods.

proportional to the relative frequency of the occurrence cases. When the climatological frequency of precipitation is very low, as in the far southwest during summer, the number of cases in the wet class may be insufficient to give representative values of persistence. As a result, tabulated values of persistence for the wet class must be used with caution in very dry areas.

Variability of Persistence - Examination of the derived values of persistence shows that persistence varies with choice of conditional and verifying periods, geographical area, and season. The two types of persistence (wet and dry) are not independent (see Appendix A), and variations in one must be accompanied by comparable variations in the other. For given climatic conditions, an increase (decrease) in wet persistence must be reflected in a decrease (increase) in dry persistence. In the following discussion, attention will be focused mainly on wet persistence.

In general, highest values of wet persistence are found for short conditional periods (e.g., W_1) and long verifying periods. This reflects the tendency for precipitation, which is occurring just prior to the verifying period, to continue on into the verifying period and to be observed more frequently for the longer verifying periods. However, the longer verifying periods have the undesirable effect of increasing the values of dry persistence. As the length of the conditional period increases (W_2 and W_3) and the verifying period decreases, wet persistence tends to diminish. Diurnal trends at individual stations may overshadow these general tendencies.

Introduction of a conditional period consisting of two consecutive time intervals, both of which are either dry or wet (e.g., W_4), would be expected to influence the value of the derived persistence. When precipitation tends to occur for prolonged periods on the average, wet persistence of this type would increase, but for short average durations it would tend to decrease. In general, this type of persistence probability (W_4, W_5, and W_6) tends to be less at most cities than the shorter period conditional persistence (W_1, W_2, and W_3). However, there are numerous exceptions. Seattle during winter shows a value of 90.8 percent for wet persistence when the conditional two 6-hour periods are wet (W_4), followed by a 00 - 24Z verifying period. This is the highest value of persistence observed for any city for any season. Albany and Albuquerque have W_4 as their highest values of wet persistence in spring, compared to other values of persistence for the same season, and Richmond and Salt Lake City have similar highest values for summer. However, it is not the purpose here to examine how each area responds to varying combinations of conditional and verifying periods. Data for each city can be examined when the city is of special interest. As the lengths of the conditional periods increase (W_5 and W_6), persistence decreases.

With the introduction of a 6-hour lapse between the conditional and verifying periods (Type C combinations of periods), it would be expected that values of wet persistence would decrease. This trend is generally observed in the tabulated data, with W_7 being less than W_1, W_8 less than W_2, and W_9 less than W_3.

Variations of persistence probability with geographical area and seasons largely reflect climatic differences. Some areas exhibit highest values in winter, such as the north Pacific Coast and the Great Lakes region, while other areas may have their highest values in summer, e.g., Florida and the Gulf Coast. Seasonal variations at individual cities may be noted by examining the data for the several seasons.

Example Showing Seasonal and Geographical Variations in Persistence - To illustrate the manner in which persistence varies with season and geographical area, charts showing wet and dry types of persistence are given in figures 2 and 3 for the winter and summer seasons. Data used for these charts appear in columns W_1 and D_1 of the tabulated data and are for a 6-hour conditional period and a 12 - 12Z verifying period.

Figure 2 gives the analyses for winter when the conditional period is wet (Part A) and when the period is dry (Part B). For the wet cases, it is observed that the highest values recorded occur along the North Pacific Coast, where an area greater than 80 percent prevails. A broad area of minimum values extends from the Texas Panhandle northward through the Great Plains, where values range below 60 percent. Areas of over 70 percent occur in the Great Lakes region, the southern Appalachians, the Ohio Valley, the North Atlantic Coast, Utah, and eastern Texas and southern Arkansas.

Several cities are found to have strong diurnal effects when persistence probabilities for the 12 - 12Z period are compared with those for the 00 - 24Z period. These cities have been starred on the charts for which differences of 10 percent or more in the two values are observed. For example, Pensacola with a 60 percent on the chart shown (Part A) has a 76-percent value for the 00 - 24Z period.

When the conditional 6-hour period is dry, a substantial reduction in persistence probability is observed, as shown in Part B of figure 2. Here maximum values of 50 percent are found in the eastern Great Lakes region, and minimum values of less than 10 percent are observed over a broad area in the Southwestern States.

Similar data and analyses are given in figure 3 for the summer season. The most striking change in wet persistence (Part A) compared to winter is the strong maximum which has developed over Florida and the Gulf Coast. Persistence probabilities in this area also show a large diurnal effect, as indicated by the many starred cities. Persistence probabilities have diminished in the Great Lakes region and in the Far West. A more variable pattern is observed in the central part of the country, but with most areas showing a decrease from winter. For dry persistence (Part B), values are higher than winter over the central and northern Great Plains, but lower in the Western States and in the area of the Great Lakes. In the East, higher values are observed along the Gulf Coast and in Florida, but with little change northward over the Atlantic Coast States.

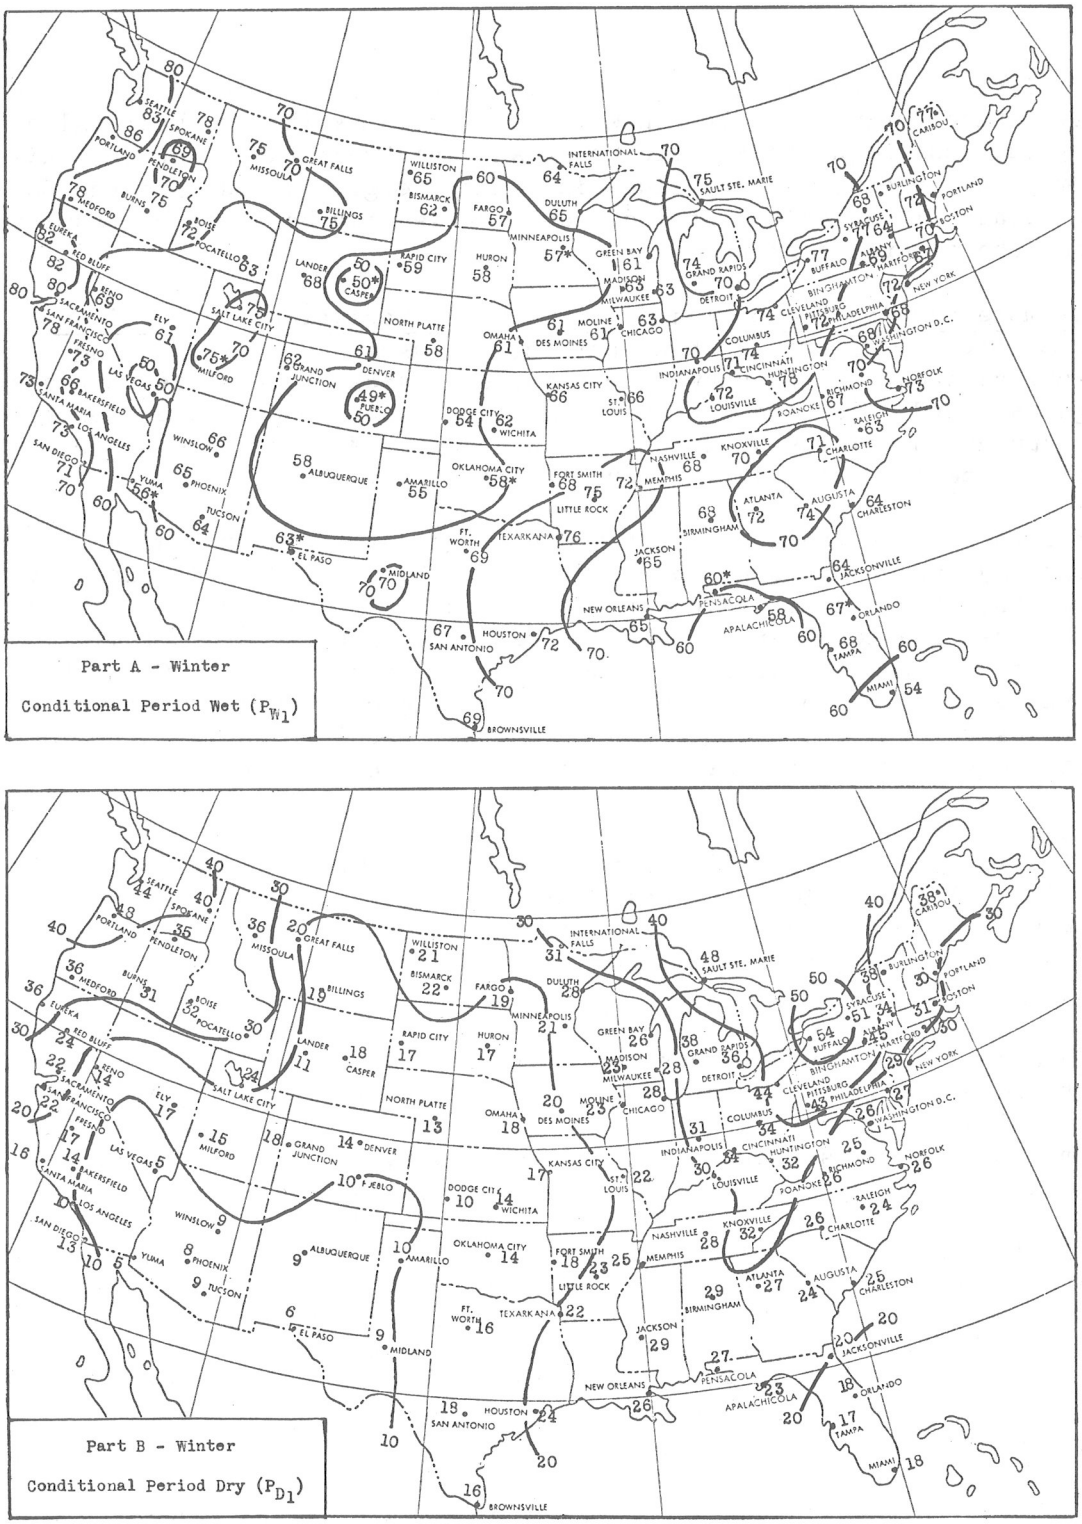

Figure 2. - Charts giving persistence probabilities of precipitation ($\geq$.01 inch) during the 12 - 12Z verifying period for winter when the conditional 06 - 12Z period is wet (Part A) and dry (Part B).

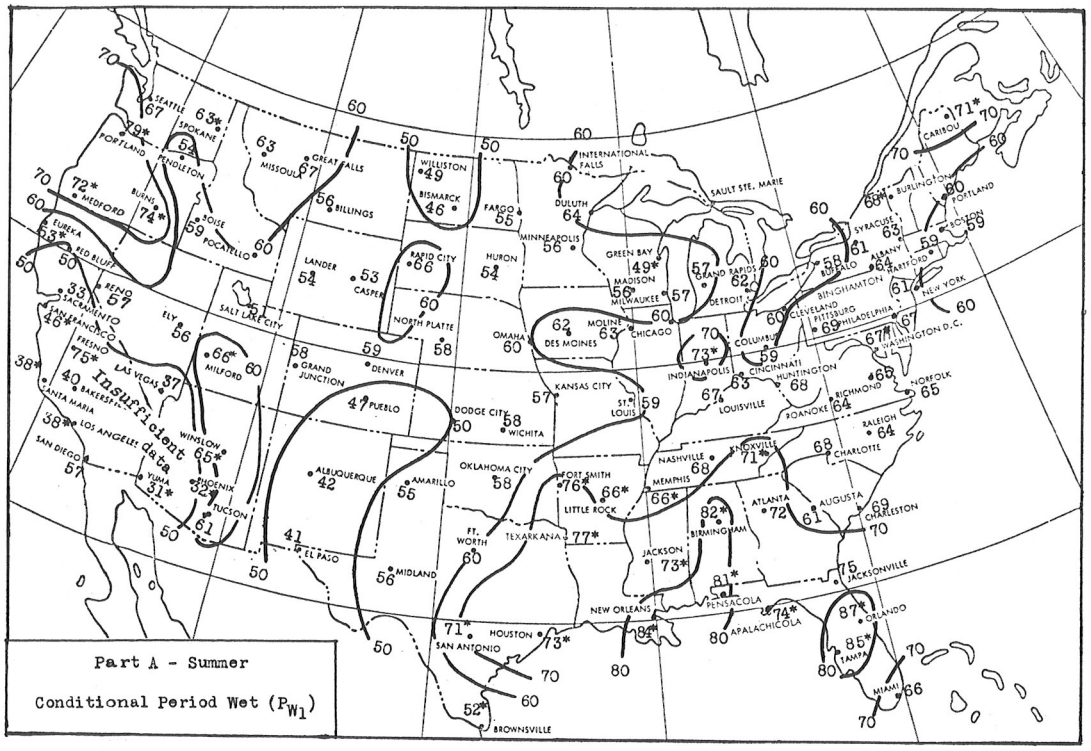

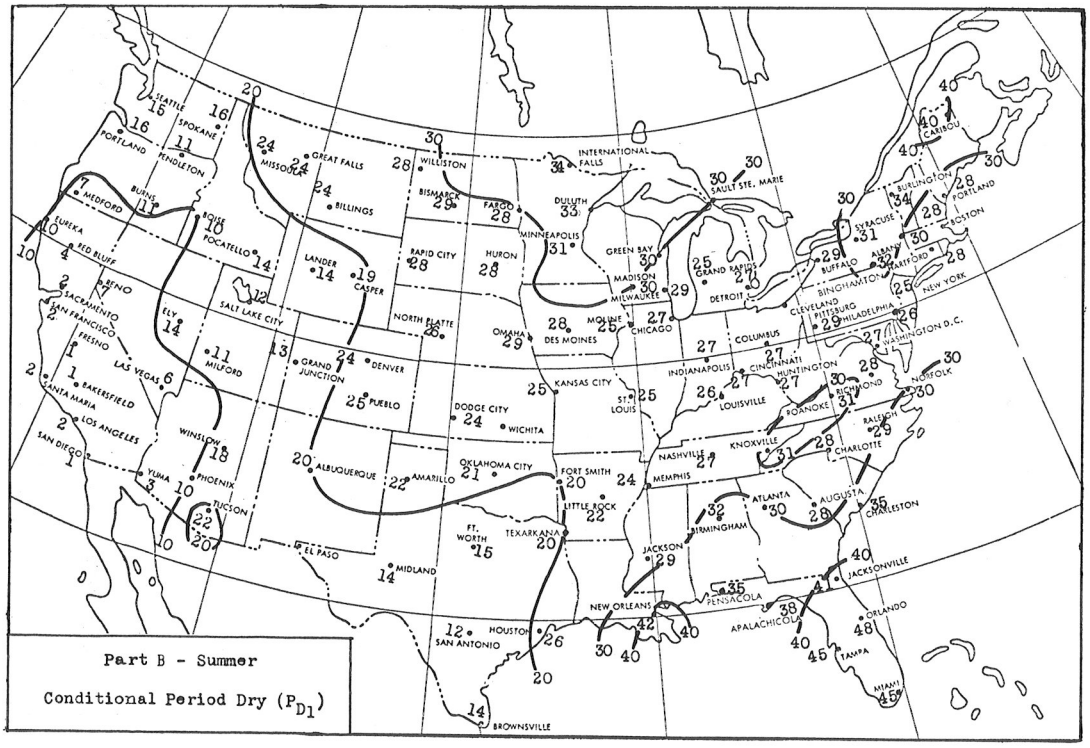

Figure 3. - The same as figure 2 except for summer.

Charts of the same type can be constructed for spring and fall and for other combinations of conditional and verifying periods.

OPERATIONAL USE OF PERSISTENCE PROBABILITIES

Persistence can be of substantial help to the forecaster in evaluating the probability of future weather in terms of that which has just occurred. Experience shows, especially in very wet or dry climates, that it is difficult to "beat persistence" in precipitation forecasting. At Seattle, for instance, the persistence probability of precipitation of 91 percent during the 00 - 24Z period in winter, following two wet 6-hour periods, is difficult to improve upon. Conversely, when the two preceding periods are dry, the derived probability of 42 percent represents a significant diminution from climatology in this wet area [7]. In the dry Southwest, the probability of 66 percent that precipitation will occur in the 12 - 12Z period at Winslow during winter when the previous 6-hour period is wet furnishes significant information to the forecaster. This contrasts to a value of only 9 percent when the previous period is dry. Comparable data extracted from figure 2 are: for Chicago, 63 versus 28 percent; Kansas City, 66 versus 17 percent; and New York, 72 versus 29 percent. Similar comparisons can be made for other cities, other combinations of time periods, and other seasons.

In view of the fact that persistence shows substantial improvement over conventional climatological probabilities of precipitation occurrence, persistence offers a good "first guess" for the probability of precipitation based on previous weather. An inspection of the tabulated data given in Appendix B indicates that for a majority of stations, maximum values of wet persistence probabilities are obtained when using the 6-hour conditional period immediately preceding the verifying period. Values of dry persistence probabilities tend to decrease with increasing length of conditional periods, but the differences are too small to be of practical significance. This suggests that, as a general rule, the two columns headed D_1 and W_1 may be of greatest value to the forecaster. In a small percentage of cases, uncertainty may be encountered as to whether precipitation will occur in the conditional period between the time the forecast is completed and the beginning of the forecast period (i.e., during the last 2 or 3 hours of the conditional period). In most cases, the infrequent occurrence of this situation would not justify using the 6-hour lapse between the conditional and verifying periods defined by the Type C persistence.

The derived persistence probabilities vary with the length of the conditional period and, as a result, conflicting values may occasionally be encountered. This situation might arise, for example, when precipitation occurs during the first 6 hours of a 12-hour conditional period but not during the last 6 hours. In this case, a relatively large value of W_2 might conflict with a small value for D_1. Since precipitation has apparently ceased, the D_1 value would be the most appropriate to use, but the forecaster would need to make the decision based on the synoptic situation.

The Type B persistence probabilities in which precipitation does or does not occur in both portions of the conditional period involve special situations evaluated on a subset of the data sample. When Type B conditions are fulfilled, then probability values listed under D_4 and W_4, D_5 and W_5, and D_6 and W_6 will supply useful information. As a result of the definitions of the various types of persistence, D_4 is equivalent to D_2, and D_5 is equivalent to D_3. Duplicate columns of these values are included in the tabulated data to enhance the usefulness of the table.

Examples - Although exact conditions of weather and operating needs faced by the forecaster cannot be foreseen, ranges of persistence established by the derived data can be determined. For illustrative purposes, conditional periods have been examined for three cities to obtain the ranges of values exhibited between dry persistence and wet persistence for the eight verifying periods. In practice, values of persistence obtained from the derived data would fall between these extremes, depending on the conditional period employed. These data are presented in table 1 for San Francisco and Chicago for winter, and for Pensacola for summer. Climatological frequencies of precipitation obtained from an earlier study [9] are presented for comparative purposes.

At San Francisco, persistence indicates a 4 to 5 percent probability of rain during a 6-hour verifying period when the conditional 48-hour period is dry (D_6), and a probability ranging from 61 to 71 percent when the one and two 6-hour conditional periods are wet (W_1 and W_4). For the two 12-hour verifying periods, the persistence probabilities range from 9 percent for dry persistence to 73 and 78 percent for wet persistence for the indicated conditional periods. Similar values for the 24-hour verifying periods are 16 and 17, and 78 and 85 percent. At Chicago, persistence is less marked than at San Francisco, even though the climatological frequencies are about the same. At Pensacola in summer, the probabilities for 6-hour verifying periods range from 4 to 12 percent for dry persistence, depending on the time of day and conditional periods, to 72 to 86 percent for wet persistence for the verifying 24-hour periods, again for the indicated combination of conditional periods. (The extended conditional periods observed at Pensacola would appear to indicate that rain occurrences (thunderstorms) are dependent on broadscale atmospheric circulation patterns rather than local effects.)

Evaluation of Persistence Forecasts - The effectiveness of persistence probability forecasts can be determined by evaluating them in terms of the P-Score. A comparison can be made with the P-Score obtained for a sample of actual forecasts, with forecasts based on long-term climatology, and with climatological forecasts verified in terms of precipitation occurrences during the sample period. The P-Score is highly dependent on the climatological frequency of the forecast event [4]. For this reason, the scores are directly comparable only when the climatology of the sample is essentially the same as that for the longer term period. Also, it should be recognized that the actual forecasts are completed prior to the beginning of the verifying period, which gives a slight advantage to the persistence forecasts. In the evaluation that follows, forecasts for two winter and two summer seasons for a selected number of stations will be used for comparative purposes.

Table 1. - Data giving observed minimum values of dry persistence and maximum values of wet persistence with the associated conditional period for each of the eight verifying periods for three cities. Data are obtained from the table in Appendix B. Climatological relative frequencies of precipitation are included.

San Francisco, Winter

Verifying Period	Climatological Frequency (%)	Minimum Dry Persistence		Maximum Wet Persistence	
		Period	Persistence (%)	Period	Persistence (%)
00 - 06Z	17	D_6	5	W_4	71
06 - 12Z	18	D_6	4	W_4	70
12 - 18Z	20	D_6	4	W_1	70
18 - 24Z	17	D_6	5	W_1	61
00 - 12Z	24	D_6	9	W_4	78
12 - 24Z	24	D_6	9	W_1	73
00 - 24Z	33	D_6	17	W_4	85
12 - 12Z	33	D_6	16	W_4	78

Chicago, Winter

Verifying Period	Climatological Frequency (%)	Minimum Dry Persistence		Maximum Wet Persistence	
		Period	Persistence (%)	Period	Persistence (%)
00 - 06Z	16	D_6	6	W_1	60
06 - 12Z	16	D_1, D_6	8	W_1	56
12 - 18Z	16	D_2, D_4	8	W_1	54
18 - 24Z	16	D_6	7	W_4	60
00 - 12Z	23	D_6	14	W_1	63
12 - 24Z	22	D_2, D_4	15	W_4	59
00 - 24Z	34	D_6	27	W_1	66
12 - 12Z	34	D_6	27	W_1	63

Pensacola, Summer

Verifying Period	Climatological Frequency (%)	Minimum Dry Persistence		Maximum Wet Persistence	
		Period	Persistence (%)	Period	Persistence (%)
00 - 06Z	12	D_6	4	W_5	33
06 - 12Z	11	D_6	5	W_1	32
12 - 18Z	20	D_6	11	W_4	66
18 - 24Z	22	D_6	12	W_4	58
00 - 12Z	20	D_6	9	W_5	52
12 - 24Z	32	D_6	22	W_4	75
00 - 24Z	40	D_6	28	W_5	72
12 - 12Z	40	D_6	28	W_4	86

The well-known relationship between the P-Score and long-term climatology is

$$\text{P-Score (Climat.)} = C(1 - C) \qquad (1)$$

where C is the climatological relative frequency of precipitation. A comparable score can be obtained for the sample period, but with the climatological forecasts verified in terms of the actual occurrence of precipitation during the sample period. (Here and elsewhere, the P-Score varies from 0 to 1 with the lower score indicating the better forecasts.)

P-Scores can be computed for persistence probability forecasts in a manner similar to that for long-term and sample climatologies. However, persistence scores are not available for the sample, and only the long-term scores will be used in the comparison. Since persistence forecasts are made up of two types, the wet and the dry, the overall P-Score can be obtained by weighting each type according to the number of times each occurs. Therefore, we have

$$\text{P-Score (Persist.)} = p_{cp}\ [P_W(1 - P_W)] + q_{cp}\ [P_D(1 - P_D)] \qquad (2)$$

where p_{cp} is the relative frequency of precipitation in the conditional period and q_{cp} is the relative frequency of no precipitation in the same period.

As part of the forecast evaluation program of the Weather Bureau, P-Scores have been computed for forecasts issued for 100 cities in the 48 States for the past several years [13]. The P-Scores obtained by this program will be compared with the persistence and climatological scores for 14 cities for the two seasons. The use of persistence is most effective for short time periods. For this reason, persistence probability forecasts for the 06 - 12Z conditional and 12 - 24Z verifying periods have been chosen for comparison with other forecasts. Of course, the use of persistence probability forecasts in this form requires a knowledge of the weather during the 6-hour period immediately preceding the verifying period.

Table 2 presents the P-Scores for six winter months and table 3 for six summer months for the several types of forecasts. Also given are skill scores for which the P-Scores are compared with several standards. The skill score is defined as follows:

$$\text{Skill Score} = 1 - \frac{\text{P-Score}}{\text{Standard P-Score}} \qquad (3)$$

The first column in table 2 gives the P-Scores which would be obtained for climatological forecasts issued for a period for which the climatological relative frequency was observed. This score is computed using equation (1). The second column gives the P-Scores of the same forecasts, but with the verification based on the weather which actually occurred during the sample period. If the frequency of precipitation occurring during the sample period corresponded to the long-term average, these two columns would tend to be identical.

Table 2. - Tabulation giving P-Scores and Skill Scores for comparative purposes. The scores are computed for forecasts covering the first 12 hours (12 - 24Z) of the forecast period in terms of precipitation occurrence of .01 inch or more. The period of record is for the months of December, January, and February, 1967-69.

	P-Scores				Skill Scores		
	Long-term climatology	Sample climatology	Climatology persistence	Actual	Persistence vs. climatology	Actual vs. sample climatology	Actual vs. persistence
Boston	.192	.179	.147	.073	.234	.592	.504
Chicago	.172	.184	.147	.092	.144	.500	.374
Cleveland	.228	.221	.196	.145	.140	.344	.260
Ft. Worth	.128	.169	.099	.094	.227	.444	.051
Kansas City	.120	.134	.095	.097	.208	.276	-.021
Los Angeles	.106	.167	.074	.074	.302	.557	.000
Miami	.106	.090	.098	.062	.076	.311	.367
New Orleans	.166	.143	.147	.113	.120	.210	.226
New York City	.188	.154	.144	.080	.234	.481	.444
St. Louis	.141	.186	.116	.101	.177	.457	.129
Salt Lake City	.166	.164	.128	.128	.229	.220	.000
San Francisco	.182	.227	.129	.102	.286	.551	.215
Seattle	.248	.246	.189	.144	.238	.415	.238
Washington, D.C.	.172	.154	.139	.073	.192	.526	.475
Mean	.166	.173	.132	.098	.200	.420	.233

Consequently, the difference between the two columns indicates how much the sample period departs from climatology. These differences show that Ft. Worth, Los Angeles, St. Louis, and San Francisco had substantially more frequent precipitation during the sample period than would be expected from climatology, thus tending to give higher P-Scores. On the other hand, New Orleans, New York, and Washington had lower values with the converse results. The scores range from 0.090 at Miami to 0.246 at Seattle.

The third column gives the P-Scores which are obtained by using equation (2). Wet and dry persistence probability forecasts for a 6-hour conditional period and the 12 - 24Z verifying period are read from the tabulated data in Appendix B and weighted according to the relative frequency of precipitation occurrence and nonoccurrence in the conditional 6-hour period. (The weighting factors are obtained from [9].) The fourth column then gives the P-Scores attained by the official forecasts.

The final three columns in the table give skill scores computed from the P-Scores by means of equation (3). The first column under skill scores compares the P-Scores obtained by persistence with those for climatology. These figures give a good indication of the value of persistence probability forecasts for the specified conditional and verifying periods for the winter season. Highest skill for persistence forecasts is observed for stations along the West Coast, with lowest skill noted at Miami and New Orleans. Chicago, Cleveland, and St. Louis also show relatively low skill. The second column gives the skill scores of official forecasts evaluated in terms of the P-Scores obtained for climatological forecasts verified on the weather occurring during the sample period. The final column presents the skill of the actual forecasts compared to persistence. As noted from this last column, the skill of the actual forecasts compared to persistence varies widely from near zero at several stations to 0.504 at Boston

A summary of the various scores expressed as averages for the fourteen cities is given at the bottom of the table. The mean P-Scores for climatological persistence forecasts show considerable improvement over climatology, but are significantly worse than those for the official forecasts. The means of the skill scores give the average improvement of persistence forecasts over climatology, the average improvement of the official forecasts over sample climatology, and the average improvement of the same forecasts over persistence. The mean skill of 0.420 for the official forecasts versus the sample climatology is reduced to 0.233 when compared to persistence forecasts.

Table 3 gives a similar listing of scores for the summer months. Data for Los Angeles and San Francisco are not included because of the almost total lack of precipitation cases during the two summer seasons. Although the mean P-Scores for long-term and sample climatologies are only slightly lower than for winter, the P-Scores for persistence and actual forecasts are higher. These higher values indicate less persistence and a greater difficulty in forecasting precipitation occurrences in summer. These same trends are also indicated in the mean skill scores, where persistence does little

Table 3. - Same as table 2 except for months of June, July, and August, 1967-1968.

	P-Scores				Skill Scores		
	Long-term climatology	Sample climatology	Climat persistence	Actual	Persistence vs. climatology	Actual vs. sample climatology	Actual vs. persistence
Boston	.166	.172	.147	.134	.114	.221	.088
Chicago	.160	.154	.146	.110	.088	.286	.247
Cleveland	.166	.162	.153	.124	.078	.235	.190
Ft. Worth	.106	.124	.094	.096	.113	.226	-.021
Kansas City	.141	.130	.129	.098	.085	.246	.240
Los Angeles	Insufficient precipitation cases						
Miami	.228	.254	.225	.219	.013	.138	.027
New Orleans	.236	.231	.227	.195	.038	.156	.141
New York	.154	.176	.133	.135	.136	.233	-.015
St. Louis	.148	.145	.139	.104	.061	.283	.252
Salt Lake City	.082	.126	.072	.096	.122	.238	-.333
San Francisco	Insufficient precipitation cases						
Seattle	.113	.110	.088	.066	.221	.400	.250
Washington, D.C.	.154	.174	.139	.135	.097	.224	.029
Mean	.154	.163	.141	.126	.097	.240	.091

better than climatology, and where the actual versus sample climatology drops to 0.240 compared to the 0.420 attained for winter. The actual versus persistence skill score drops to less than half the value observed for winter. Thus it is very hard for the forecaster to beat persistence during the summer. It should be emphasized that the scores given here for both seasons are based on a short period of record and are not intended to indicate the on-going skill attained for the selected cities.

RELATION BETWEEN CORRELATION COEFFICIENT AND PERSISTENCE

The investigation of persistence deals with the probability of occurrence of precipitation during a specified time period in relation to whether or not precipitation occurred in an earlier period. The concept of statistical correlation may be used to express this same general type of relationship. It is of interest to determine how these two statistical approaches are related, and to examine the usefulness of each approach in describing the statistics of recurring precipitation events.

In the following sections, an example is given illustrating the type of pattern exhibited by the correlation coefficient in relating successive precipitation occurrences at the 108 cities, and a statistical equation is presented giving the relationship between the correlation coefficient and persistence.

Correlation Coefficients - To obtain the coefficients of correlation, r, we have the following expression:

$$r = \frac{\sum(x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum(x_i - \bar{x})^2 \sum(y_i - \bar{y})^2}} \qquad (4)$$

where x_i and y_i are the two variables and $\bar{x}$ and $\bar{y}$ are their average values. In our problem, the values of the two variables are either 1 or 0 depending on whether or not precipitation occurs in the specified periods, and the average values are equivalent to the relative frequencies of occurrence in the appropriate periods.

Expression (4) was used to correlate the occurrence of precipitation in the 12 - 24Z period with that occurring in the preceding 12-hour period for the 108 cities for winter for the 15-year period of record. These data have been plotted and analyzed in figure 4. Values of the correlation coefficients range from 0.24 at Yuma and Binghamton, to 0.53 at Eureka and San Diego. Highest values occur along the West Coast, the eastern slopes of the Rocky Mountains, and from Texas northeastward through the middle Mississippi Valley. Areas of high values are also observed from central Georgia northeastward into the Carolinas and in a small area along the New England coast. Values are generally lower over the western Plateau, the central and northern Great Plains, and along the gulf coast.

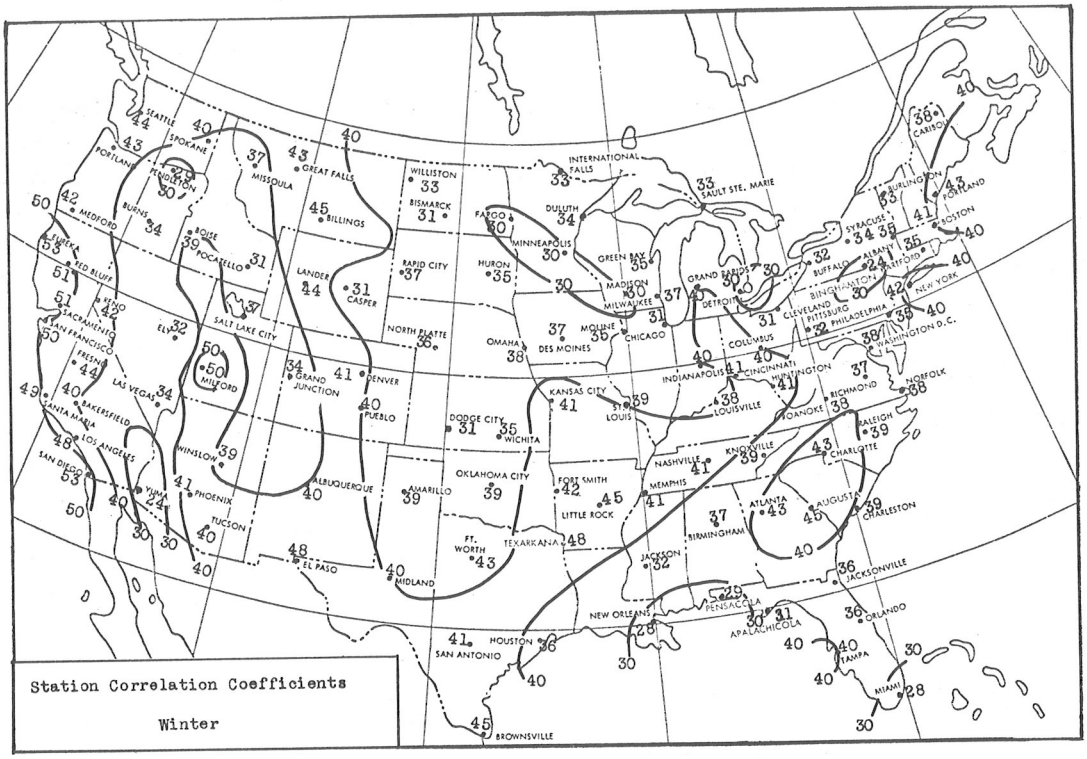

Figure 4. - Station coefficients of correlation between precipitation occurrences during two consecutive 12-hour periods (00-12Z vs. 12-24Z) for winter.

To compare persistence patterns with that shown by the correlation coefficient, analyses for wet and dry types of persistence for the same combination of periods are shown in figure 5. These charts are similar to those shown earlier (figure 3) except that a 12-hour, rather than a 6-hour, conditional period is used. Here we are attempting to compare two persistence charts with the single correlation chart. This comparison is complicated by the fact that dry persistence contributes a negative quantity to the correlation coefficient.

Since persistence and correlation involve the same variables and both approaches show statistical relationships between these variables, it is to be expected that one approach can be expressed in terms of the other. The derivation of an expression relating the coefficient of correlation given in (4) to wet and dry persistence (P_W and P_D) is described in Appendix A. The relationship obtained is as follows:

$$r = \frac{p_{cp} q_{cp} (P_W - P_D)}{\sqrt{p_{cp} q_{cp} \cdot p_{vp} q_{vp}}} \qquad (5)$$

where p_{cp} and q_{cp} are the relative frequencies of precipitation and non-precipitation occurrences, respectively, in the conditional period, and p_{vp} and q_{vp} are similar quantities for the verifying period.

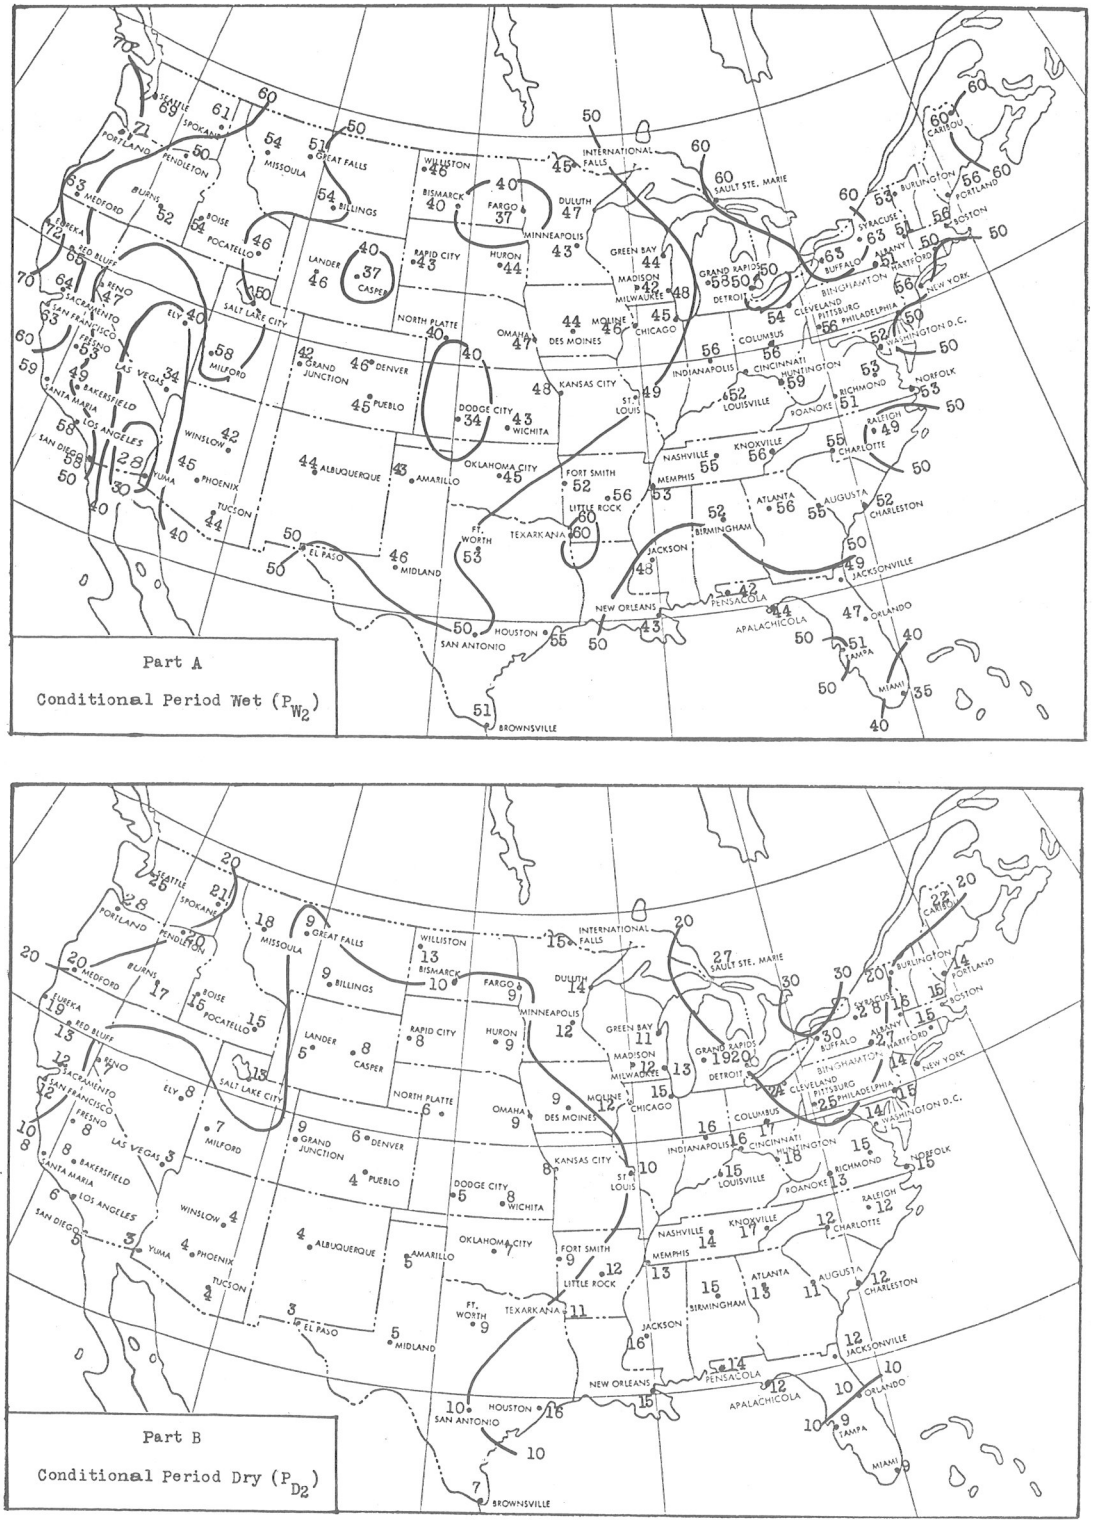

Figure 5. - Charts giving wet (Part A) and dry (Part B) persistence probabilities of precipitation for the same combination of periods used to derive the coefficients of correlation in figure 4. (Periods 00-12Z vs. 12-24Z for winter.)

From equation (5), it is noted that when the relative frequencies are the same in both the conditional and verifying periods, the relationship reduces to

$$r = P_W - P_D \tag{6}$$

This condition tends to be realized when the conditional and verifying periods are of the same length and there is little or no diurnal variation in the occurrence of precipitation. The first condition can be satisfied by the proper choice of periods. The second condition is likely to be substantially fulfilled during the winter season when diurnal effects are at a minimum. Assuming equation (6) to hold true, we would then expect the pattern exhibited by the correlation coefficient to be similar to that obtained when dry persistence is subtracted from wet persistence. This subtraction has been carried out for the two charts shown in figure 5, with the plotted data and analysis shown in figure 6. Comparison of figure 6 with the correlation coefficients in figure 4 indicates very little difference between the two patterns.

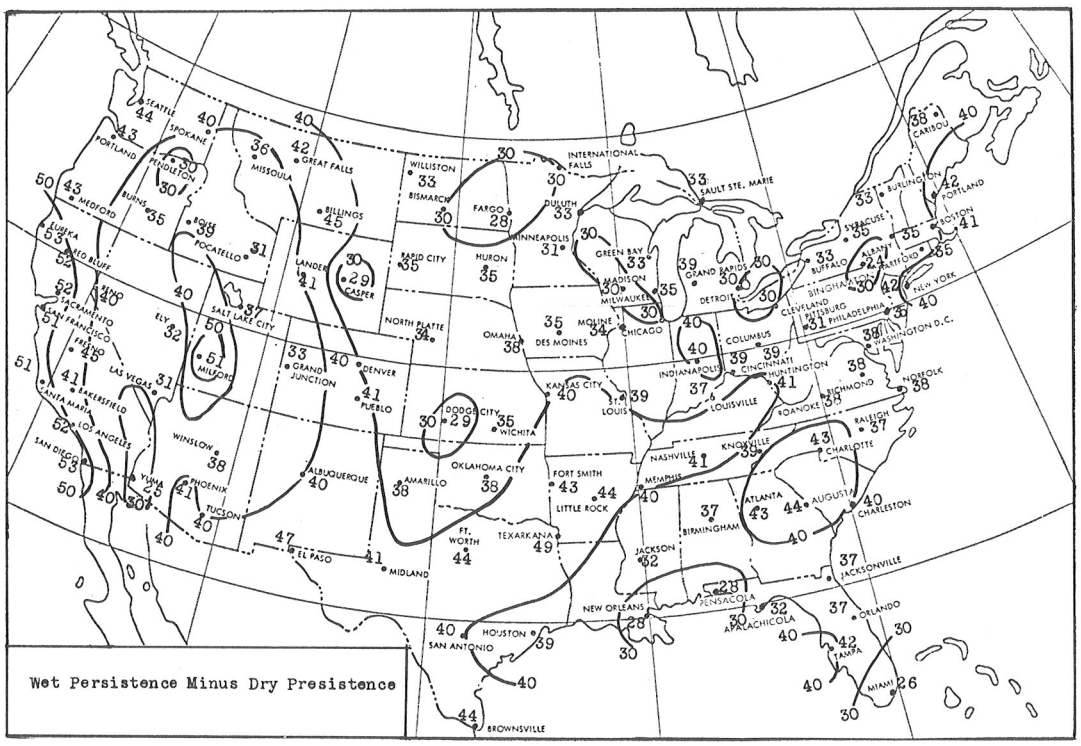

Figure 6. - Wet persistence minus dry persistence obtained from the two charts in figure 5. Station values in Part B are subtracted from corresponding values in Part A to give the difference pattern.

It is seen, then, that the correlation coefficient is related to the difference between the wet and dry values of persistence. This has important considerations in evaluating the two statistical approaches in that the difference between two quantities (e.g., $P_W - P_D$) supplies substantially less information about the quantities than can be obtained from the individual quantities themselves. As a consequence, evaluation of the tendency of precipitation to recur in the form of the two types of persistence greatly enhances the practical usefulness of the resulting information over that gained from the correlation coefficient alone.

ACKNOWLEDGMENTS

Acknowledgment is made of the partial financial support for this project furnished by the Bureau of Reclamation, Department of the Interior. Thanks are due to Dr. Harry R. Glahn for many helpful discussions and to Mr. August F. Korte for a careful reading of the manuscript. Computational work was performed by Mr. George P. Casely and Mr. Frederick Marshall of the Techniques Development Laboratory. Precipitation data were supplied by the National Weather Records Center at Asheville, N. C.

APPENDIX A

STATISTICAL FORMULATIONS

The two types of persistence probabilities described in this report are statistically related. This relationship will be described in the following sections. In addition, an expression will be derived relating the two types of persistence to the coefficient of correlation between precipitation occurrences in two successive time periods. The derived relationships will serve to give further insight into the interpretation of the persistence probabilities.

Statistical Definition of Persistence - In order to develop the desired relationships, the two types of persistence probabilities will be expressed in mathematical terms. Wet persistence (P_W) has been defined earlier in this report as the probability of precipitation occurrence in the verifying period following a wet conditional period, and dry persistence (P_D) the probability of precipitation occurrence following a dry conditional period. Using the two variables in (4), P_W and P_D can be expressed in terms of x_i and y_i, where, again, x_i represents the occurrence ($x_i = 1$) or non-occurrence ($x_i = 0$) of precipitation in the conditional period, and y_i represents similar values for the verifying period. The probabilities giving the two types of persistence can then be written as follows:

$$P_W = \frac{\sum x_i y_i}{\sum x_i}, \text{ and} \tag{1A}$$

$$P_D = \frac{\sum y_i - \sum x_i y_i}{\sum (1 - x_i)} \tag{2A}$$

where the summations are taken over all cases (N) in the data sample.

In (1A), the numerator ($\sum x_i y_i$) gives the number of times in the data sample that precipitation in the conditional period ($x_i = 1$) is followed by precipitation in the verifying period ($y_i = 1$). All other combinations of $x_i y_i$ are equal to zero. The denominator then gives the total number of precipitation cases in the conditional period with the ratio furnishing the desired probability for wet persistence.

The expression (2A) gives a similar ratio defining dry persistence. Here, the numerator gives the total number of precipitation cases occurring in the verifying period ($\sum y_i$) less those cases which were preceded by a wet conditional period ($\sum x_i y_i$). This furnishes the number of precipitation cases in the verifying period preceded by a dry conditional period. The denominator gives the number of dry cases in the verifying period, thus giving the required probability ratio.

Relationship between Wet and Dry Persistence - It is well to point out at the outset that the persistence probabilities obtained for the wet and dry conditional periods are not independent. In (1A) and (2A) we note that the quantity $\sum x_i y_i$ is common to both expressions. Eliminating this quantity between the two, we have

$$\sum x_i P_W + \sum (1 - x_i) P_D = \sum y_i \qquad (3A)$$

Using the more convenient notation defined earlier, we can write

$$p_{cp} P_W + q_{cp} P_D = p_{vp} \qquad (4A)$$

where $\sum x_i = Np_{cp}$, $\sum (1 - x_i) = Nq_{cp}$, and $\sum y_i = Np_{vp}$, with the number of cases (N) canceling out.

From (4A), we see that P_W and P_D are related through the relative frequencies of precipitation in the conditional and verifying periods. Knowing these quantities, either P_W or P_D can be determined once the other is known.

Separation of Persistence into Two Terms - In interpreting the derived results, it is of interest to consider persistence as being made up of two terms. The first term is equal to the climatological relative frequency of precipitation occurrence in the verifying period (p_{vp}) and the second the amount by which the computed persistence differs from this relative frequency. We can write:

$$P_W = p_{vp} + d_w, \text{ and} \qquad (5A)$$

$$P_D = p_{vp} - d_d \qquad (6A)$$

where d_w is the difference, expressed as a relative frequency, between persistence and the relative frequency in the verifying period for the wet cases, and d_d is the difference for the dry cases. (In a sense, the values of d represent "real persistence" since the p_{vp} component does not depend on the previous weather.) In considering (5A), it can be seen that for very wet climates the climatological relative frequency of precipitation must furnish the major contribution to wet persistence. From (6A), it is seen that d_d must always be smaller than p_{vp} as long as P_D is positive.

The values of d_w and d_d are not equivalent in general. By substituting (5A) and (6A) into (4A) and solving in terms of the differences, we obtain the following relationship:

$$\frac{d_w}{d_d} = \frac{q_{cp}}{p_{cp}} \qquad (7A)$$

Therefore, the ratio d_w/d_d depends only on the relative frequency of precipitation in the conditional period ($q_{cp} = 1 - p_{cp}$). If $p_{cp} = .5$, for example, $d_w = d_d$ and the associated P_W will exhibit the same departure above the value of pvp as P_D falls below it. If $p_{cp} = .2$, d_w will have four times the value

of d_d, and the values of the two persistences will vary accordingly. Of course, the relation given in (7A) supplies no information as to the actual magnitudes of d_w and d_d, and these must be obtained from the basic data.

Relationship Between the Correlation Coefficient and Persistence - Using the expression for the coefficient of correlation from (4) and the definitions of P_W and P_D from (1A) and (2A), we can now develop a relationship between the coefficient of correlation and persistence. The numerator of (4) can be expanded as follows:

$$\sum(x_i - \bar{x})(y_i - \bar{y}) = \sum x_i y_i - N\bar{x}\bar{y} \tag{8A}$$

with $\sum x_i = N\bar{x}$, $\sum y_i = N\bar{y}$, and $\sum \bar{x}\bar{y} = N\bar{x}\bar{y}$ in carrying out the expansion. From (1A) and (2A), we see that $\sum x_i y_i = \sum x_i P_W = N\bar{x}P_W$, and $N\bar{y} = N(1 - \bar{x})\ P_D + N\bar{x}\ P_W$. Substituting these values into (8A) and simplifying gives the numerator as follows:

$$\sum(x_i - \bar{x})(y_i - \bar{y}) = N\bar{x}(1 - \bar{x})(P_W - P_D) \tag{9A}$$

In a similar manner, and using the identities $x_i^2 = x_i$ and $y_i^2 = y_i$, the denominator of (4) can be written

$$\sqrt{\sum(x_i - \bar{x})^2\ \sum(y_i - \bar{y})^2} = \sqrt{N\bar{x}(1 - \bar{x})\cdot N\bar{y}(1 - \bar{y})} \tag{10A}$$

We then have for the coefficient of correlation

$$r = \frac{\bar{x}(1 - \bar{x})(P_W - P_D)}{\sqrt{\bar{x}(1 - \bar{x})\bar{y}(1 - \bar{y})}} \tag{11A}$$

Expressing the coefficient of correlation in the more convenient notation used earlier, we have

$$r = \frac{p_{cp}q_{cp}(P_W - P_D)}{\sqrt{p_{cp}q_{cp}\cdot p_{vp}q_{vp}}} \tag{12A}$$

where $\bar{x} = p_{cp}$, $1 - \bar{x} = q_{cp}$, and similarly for the y terms. This is the desired expression relating the coefficient of correlation and the two types of persistence.

Equations (5A) and (6A) express P_W and P_D in terms of the relative frequency of precipitation in the verifying periods and the associated differences. Substituting these values of the two types of persistence into (12A) gives

$$r = \frac{p_{cp}q_{cp}(d_w + d_d)}{\sqrt{p_{cp}q_{cp}\cdot p_{vp}q_{vp}}} \tag{13A}$$

from which we see that the coefficient of correlation is proportional to the sum of the differences. This relationship would be expected, since the

correlation coefficient is a function of the differences between the two variables involved and their associated means.

APPENDIX B

DERIVED PERSISTENCE PROBABILITIES FOR 108 CITIES

Persistence determinations discussed in the main portion of this report are presented in tabular form in table 1B of this appendix. The basic data on which these derivations are made consist of 15 years of precipitation records for the period Dec. 1949 through Nov. 1964. Persistence is determined for each of the cities by seasons on the condition that precipitation occurred ($\geq$0.01 inch) or did not occur ($<$0.01 inch) in the conditional (preceding) period for eight verifying periods consisting of four 6-hour, two 12-hour, and two 24-hour periods.

Table 1B. - Persistence data for 108 cities by seasons. Persistence is expressed as a conditional probability of precipitation occurrence ($\geqslant$ .01 inch) during the verifying period, the condition being that precipitation did not occur (D values) or did occur (W values) in the preceding conditional period or periods. The following codes are used to identify the types of persistence and the conditional periods in the table:

D_1 = conditional probability of precipitation in the verifying period when the immediately preceding 6-hour conditional period is dry.

W_1 = same as D_1 except the 6-hour conditional period is wet.

D_2 = same as D_1 except the conditional period is 12-hours long.

W_2 = same as W_1 except the conditional period is 12-hours long.

D_3 = same as D_1 except the conditional period is 24-hours long.

W_3 = same as W_1 except the conditional period is 24-hours long.

D_4 = same as D_1 except the conditional period consists of two 6-hour intervals, both dry.

W_4 = same as W_1 except the conditional period consists of two 6-hour intervals, both wet.

D_5 = same as D_1 except the conditional period consists of two 12-hour intervals, both dry.

W_5 = same as W_1 except the conditional period consists of two 12-hour intervals, both wet.

D_6 = same as D_1 except the conditional period consists of two 24-hour intervals, both dry.

W_6 = same as W_1 except the conditional period consists of two 24-hour intervals, both wet.

D_7 = same as D_1 except the conditional period is the 6-hour interval ending 6 hours prior to the verifying period.

W_7 = same as W_1 except the conditional period is the 6-hour interval ending 6 hours prior to the verifying period.

D_8 = same as D_7 except the conditional period is 12-hours long.

W_8 = same as W_7 except the conditional period is 12-hours long.

D_9 = same as D_7 except the conditional period is 24-hours long.

W_9 = same as W_7 except the conditional period is 24-hours long.

(Continued from inside front cover)

WBTM TDL 16 Objective Visibility Forecasting Techniques Based on Surface and Tower Observations. Donald M. Gales, October 1968. (PB-180 479)

WBTM TDL 17 Second Interim Report on Sea and Swell Forecasting. N. A. Pore and Lt. W. S. Richardson, USESSA, January 1969. (PB-182 273)

WBTM TDL 18 Conditional Probabilities of Precipitation Amounts in the Conterminous United States. Donald L. Jorgensen, William H. Klein, and Charles F. Roberts, March 1969. (PB-183 144)

WBTM TDL 19 An Operationally Oriented Small-Scale 500-Millibar Height Analysis. Harry R. Glahn and George W. Hollenbaugh, March 1969. (PB-184 111)

WBTM TDL 20 A Comparison of Two Methods of Reducing Truncation Error. Robert J. Bermowitz, May 1969. (PB-184 741)

WBTM TDL 21 Automatic Decoding of Hourly Weather Reports. George W. Hollenbaugh, Harry R. Glahn, and Dale A. Lowry, July 1969. (PB-185 806)

WBTM TDL 22 An Operationally Oriented Objective Analysis Program. Harry R. Glahn, George W. Hollenbaugh, and Dale A. Lowry, July 1969. (PB-186 129)

WBTM TDL 23 An Operational Subsynoptic Advection Model. Harry R. Glahn, Dale A. Lowry, and George W. Hollenbaugh, July 1969. (PB-186 389)

WBTM TDL 24 A Lake Erie Storm Surge Forecasting Technique. William S. Richardson and N. Arthur Pore, August 1969. (PB-185 778)

WBTM TDL 25 Charts Giving Station Precipitation in the Plateau States From 850- and 500-Millibar Lows During Winter. August F. Korte, Donald L. Jorgensen, and William H. Klein, September 1969. (PB-187 476)

WBTM TDL 26 Computer Forecasts of Maximum and Minimum Surface Temperatures. William H. Klein, Frank Lewis, and George P. Casely, October 1969. (PB-189 105)

WBTM TDL 27 An Operational Method for Objectively Forecasting Probability of Precipitation. Harry R. Glahn and Dale A. Lowry, October 1969. (PB-188 660)

WBTM TDL 28 Techniques for Forecasting Low Water Occurrences at Baltimore and Norfolk. Lt. (jg) James M. McClelland, USESSA, March 1970. (PB-191 744)

WBTM TDL 29 A Method for Predicting Surface Winds. Harry R. Glahn, March 1970. (PB-191 745)

WBTM TDL 30 Reserved.
