PUBLICATION THESIS OPTION

This thesis has been prepared in the style utilized by the Journal of the Hydraulics Division, American Society of Civil Engineers. Pages 1-65 will be presented for publication in that journal. The Vita has been added for purposes normal to thesis writing. Additional experimental data and the simulation computer program are contained within reference (12), "Simulation Program for the Transient Hydraulics Produced by Gradually Breached Dams," Hydraulic Series Bulletin, Civil Engineering Studies, University of Missouri-Rolla, Rolla, Missouri, May 1971.
TRANSIENT HYDRAULIC SIMULATION: BREACHED EARTH DAMS

By Danny L. Fread¹, M. ASCE

KEY WORDS: breach; computer; earth dams; hydraulics; method of characteristics; numerical model; reservoirs; simulation; St. Venant equations; transient open-channel flow.

Abstract: A conceptual method to alleviate flood damages due to overtopping failures of small earthfill dams is the incorporation of a relatively thin erosion retarding layer within the dam. This paper investigates the reduction in the reservoir release due to the hypothetical erosion retarding layer. In addition, the paper provides a method for the determination of an optimal location of the layer so as to minimize the maximum possible reservoir release due to a gradually breached earth dam. The transient reservoir flow is simulated by a numerical model, based upon the solution of the one-dimensional St. Venant unsteady open-channel flow equations. These equations are solved by the method of characteristics, with appropriate boundary conditions incorporated into the solution procedure. The numerical simulation model is used to determine the reduction in reservoir release due to a single retarding layer and its optimal location for a wide range of pertinent geometric, hydraulic and dynamic parameters. The sensitivity of the results to variations in the above parameters is discussed.

INTRODUCTION

Numerous small homogeneous earthfill dams, up to approximately 100 ft. in height, have failed or are subject to possible failure from over-topping because of inadequate spillways (20, 31).\textsuperscript{2} Such failures may cause considerable property damage and even the loss of life. Inadequate spillways prevalent on many dams are generally due to the lack of engineering consultation during design and construction; however, even with engineering advice, incomplete or unavailable hydrologic data may result in the spillway being designed for less than the critical storm, resulting in the eventual failure or breach of the structure.

A conceptual method of alleviating downstream damages from breached earth dams is to provide a relatively thin erosion retarding layer at an optimal elevation within the dam. Thus, in the event of an over-topping of the dam, the resulting breach would not develop continuously but rather be delayed by the hypothetical erosion retarding layer. Such a controlled breach would produce two distinct flood waves of a reduced amplitude compared to the single flood wave produced by a breach of an earth dam without a retarding layer. Consequently, a reduction in downstream damages would be obtained.

In this paper, the hydraulic characteristics of transient reservoir flow resulting from gradually breached earthfill dams are investigated in order to ascertain the reduction of the flood wave peak due
to a retarding layer. This reduced flood wave peak discharge is shown to be directly attributable to the retarding layer's effect in reducing the reservoir outflow.

Basic assumptions concerning the geometric and dynamic aspects of the phenomenon are made in order to develop a generalized numerical simulation model of the transient reservoir flow due to a breached dam. An experimental model is used to verify the numerical model. The numerical model is used to determine the expected reduction in outflow due to a single retarding layer for several pertinent geometric, dynamic, and hydraulic parameters. Also, the elevation of the retarding layer is optimized such that the maximum possible outflow from a gradually breached dam is minimized.

THEORY

St. Venant Differential Equations. - The basis for formulating a numerical simulation model of the transient reservoir flow due to a gradually breached dam is the premise that such a phenomenon is well-approximated by the one-dimensional differential equations of gradually varied, unsteady channel flow. These equations are attributed to A.J.C. Barre' de Saint-Venant and are known as the "St. Venant equations". They are derived in several references (5,11,15,25,27) and are simply stated herein as

\[
\frac{\partial h}{\partial t} + D \frac{\partial h}{\partial x} + v \frac{\partial h}{\partial x} = 0 \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldot
in which \( y \) = the depth of flow in the channel, \( v \) = the average velocity across a section of channel, \( D \) = the hydraulic mean depth which is equivalent to \( A/T \), \( T \) = the width of the free water surface, \( A \) = the cross-sectional area, \( g \) = the acceleration due to gravity, \( x \) = the distance along the channel, and \( t \) = the time. In this paper, the channel (reservoir) is prismatic, and \( S_o \) = the slope of the reservoir bottom which is small and is approximated by \( \sin \theta \), where \( \theta \) is the angle of inclination of the reservoir bottom with a horizontal datum line. Hydrostatic conditions exist throughout the flowing fluid, and the resistance to flow due to the shear force at the wetted perimeter \( P \) is accounted for by use of Manning's equation for steady uniform flow. Thus, the friction slope \( S_f \), which is the slope of the energy grade line, can be approximated by

\[
S_f = \frac{n^2 |v| v}{2.5 R^{4/3}} \quad \text{...(3)}
\]

in which \( n \) = the Manning coefficient, and the hydraulic radius \( R = A/P \). Hence, the St. Venant equations, which are quasi-linear hyperbolic partial differential equations, describe the transient flow within the element of water that is bounded by two vertical cross sections shown in Fig. 1. Eq. 1 is known as the "equation of continuity" and mathematically expresses the Law of Conservation of Mass of the incompressible fluid within the element. Eq. 2, which is derived from Newton's Second Law of Motion, is known as the "equation of motion" and expresses the Law of Conservation of Momentum of the fluid within the element.

The initial condition of the flow within the reservoir, i.e. the depths and velocities, must be known in order that solutions to the
FIGURE 1. ELEMENTARY CHANNEL REACH
St. Venant equations may be obtained. The initial condition of the flow may be steady gradually varied, unsteady gradually varied, or steady uniform flow, etc.

Boundary conditions at the upstream and downstream extremities of the reservoir are essential to the solution of the St. Venant equations. A boundary condition is a known relationship between any two of the variables v, y, t and the flow rate Q throughout the time that solutions to the equations are desired. The upstream boundary condition, used in this paper, is a known relationship between $Q_u$ and t, i.e. $Q_u = Q_u(t)$. The downstream boundary is provided by a stage-discharge relationship, i.e. $Q_d = Q_d(y)$. The downstream boundary is located a short distance upstream of the breached dam at a section where the flow is well-approximated as one-dimensional and the surface drawdown due to the outflow through the spillway and breach is negligible.

Reservoir Geometry. - The reservoir cross section is assumed trapezoidal with side slopes of 1:vertical to z:horizontal, as shown in Fig. 2. Only the prismatic portion of the idealized reservoir shown in Fig. 3 is considered to contribute to the outflow released by a breached dam. The storage in the upper reaches of the reservoir provides little contribution to the outflow since accumulated sediment deposits soon reduce this storage to a negligible quantity. Thus, the upstream boundary is located at the upper end of the prismatic reservoir, a distance L from the downstream boundary.

The reservoir bottom slope, $S_o$, is constant and defined as

$$S_o = \frac{n}{L}, \quad \text{.................................................(4)}$$
FIGURE 2. RESERVOIR CROSS SECTION WITH EARTHFILL DAM
FIGURE 3. IDEALIZED RESERVOIR
where \( \eta \) is the height of the dam and \( L' \) is the distance from the downstream boundary to the intersection with the reservoir bottom of a horizontal line drawn from the top of the dam, as shown in Fig. 3. In this investigation, \( L \) is defined as

\[
L' = K_1 L
\]

(5)

where \( K_1 \) is a constant.

**Breach Geometry and Dynamics.** - The breach is assumed to commence forming at the instant the maximum capacity \( Q_o \) of the emergency and/or principal spillway is exceeded and the dam is over-topped. Referring to Fig. 2, the spillway is located at an elevation \( \eta_{sp} \), and the breach is assumed to form as a "V" where the acute central angle \( \phi \) of the "V-breach" remains constant throughout its formation. This breach geometry is assumed to approximate that caused by the over-topping of a homogeneous earthfill dam (31).

The breach forms at a rate denoted by \( \lambda \), which has dimensions of fps, and is defined as the vertical distance traversed by the bottom-most point of the V-breach during an increment of time. Two basic types of failure rates, \( \lambda \), are investigated herein. The first type is

\[
\lambda = \lambda_c
\]

(6)

where \( \lambda_c \) is constant for a particular interval of time during the failure or for a particular span of vertical distance within the dam; \( \lambda \) may be expressed as a step-function of either time or elevation. For the other type of failure rate, \( \lambda \) is assumed to be an exponential function of the head on the V-breach, where the head is defined as \( (y_d - \eta_y) \).

Thus,
\[
\lambda = \exp\left[K_e(y_d - \eta_v)\right] - 1 \tag{7}
\]

where
\[
K_e = \frac{\ln(1 + \lambda_m)}{y_{dm}} \tag{8}
\]

and \(y_d\) is the transient reservoir depth at the downstream boundary, \(\eta_v\) is the elevation of the bottom of the V-breach, and \(\lambda_m\) and \(y_{dm}\) are respectively the maximum failure rate and reservoir depth at the downstream boundary when \(\eta_v = 0\). When the bottom point of the V-breach is in contact with the erosion retarding layer, the failure rate is significantly reduced to a value of \(\lambda/K_\lambda\), where \(K_\lambda\) is a constant greater than unity. The top of the erosion retarding layer is denoted as \(\eta_{lt}\), the bottom as \(\eta_{lb}\), and the thickness as \(\eta_{ld}\).

**NUMERICAL SIMULATION MODEL**

**Dimensional and Geometrical Considerations.** - The St. Venant equations are nondimensionalized herein by defining the following dimensionless variables

\[
y^* = \frac{y}{\eta}, \quad v^* = \frac{v}{\eta}, \quad x^* = \frac{x}{L}, \quad t^* = \frac{t \eta}{L} \tag{9}
\]

\[
D^* = \frac{D}{D_\eta} = \frac{c_1(c_1y^* - 2c_2y^* + c_2y^{*2})}{(c_1 - c_2)(c_1 - 2c_2 + c_2y^*)} \tag{10}
\]

\[
R^* = \frac{R}{R_\eta} = \frac{(c_1 - 2c_2 + c_3)(c_1y^* - 2c_2y^* + c_2y^{*2})}{(c_1 - c_2)(c_1 - 2c_2 + c_3y^*)} \tag{11}
\]

in which 
\[
c_1 = \frac{L}{\tau}, \quad c_2 = z\eta, \quad c_3 = 2\eta\sqrt{1 + z^2} \tag{12}
\]

and \(\tau\) is the ratio of the reservoir top width \(T\) to the reservoir length \(L\). The \(\eta\) subscript indicates that the subscripted variable is evaluated
at the downstream boundary when $t = 0$, $\eta_\nu = \eta$. The * superscript is used henceforth to denote a variable as being dimensionless.

Substitution of Eq. 3 along with the above dimensionless variables into Eqs. 1 and 2, taking care to properly express the partial derivatives, yields the following dimensionless form of the St. Venant equations

$$\frac{\partial \eta^*}{\partial t} + K_1 D^* \frac{\partial \eta^*}{\partial x} + v^* \frac{\partial \eta^*}{\partial x} = 0 \quad \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots (13)$$

$$\frac{\partial v^*}{\partial t} + v^* \frac{\partial v^*}{\partial x} + K_2 \frac{\partial \eta^*}{\partial x} + \frac{K_3 |v^*| \eta^*}{R^* 4/3} - K_4 = 0 \quad \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots (14)$$

where

$$K_1 = \frac{(c_1 - c_2)}{c_1} \quad \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots (15)$$

$$K_2 = \frac{g \eta^3 (c_1 - c_2)^2}{Q_o^2} \quad \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots (16)$$

$$K_3 = \frac{g n^2 L}{2.21 n^4/3} \left[ (c_1 - 2 c_2 + c_3) \right]^{4/3} \quad \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots (17)$$

$$K_4 = \frac{g S_o \ln^2 (c_1 - c_2)^2}{Q_o^2} \quad \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots (18)$$

The following dimensionless variables are defined in order that the boundary conditions may be expressed in dimensionless form

$$\lambda^* = \frac{\lambda L}{Q_o^2 (c_1 - c_2)} \quad , \quad Q_u^* = \frac{Q_u}{Q_o^2} \quad , \quad Q_d^* = \frac{Q_d}{Q_o^2} \quad \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots (19)$$

$$\eta^*_s p = \frac{\eta_s p}{\eta} \quad , \quad \eta^*_v = \frac{\eta v}{\eta} \quad , \quad \eta^*_l t = \frac{\eta l t}{\eta} \quad , \quad \eta^*_l b = \frac{\eta l b}{\eta} \quad ,$$

$$\eta^*_l d = \frac{\eta l d}{\eta} \quad \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots (20)$$
The u and d subscripts refer to the upstream and downstream boundaries, respectively.

The above normalizing procedure allows $y^*$ and $\eta^*_v$ to take on values from unity to zero and $v^*$ and $Q^*$ to assume values relative to an initial condition of unity. Also, this procedure allows the initial flow $Q_0$ to be expressed in terms of the dimensionless failure rate $\lambda^*$. This normalizing procedure is utilized for convenience in the presentation of results.

**Initial Conditions.** - Immediately prior to the initiation of the breach, the depths and velocities along the reservoir are those of a steady, gradually varied flow having a flowrate of $Q_0$. The flow profile is either M1 or S1 backwater curve depending upon $S_0$ being either mild (See Fig. 3) or steep, for the steady flow rate $Q_0$. In either case, the flow is subcritical in the portion of the reservoir with storage that contributes to the outflow when the dam is breached.

Referring to Fig. 1, depth and velocities at $\delta x$ intervals of length along the reservoir may be computed from the steady, gradually varied flow equation (5, 15) which expressed in difference form, is

$$\frac{\delta(y+v^2/2g)}{\delta x} = S_0 - S_f \quad \text{.................................(21)}$$

where $S_f$ is defined as the average friction slope along the $\delta x$ reach, i.e.

$$S_f = \frac{S_f^1 + S_f^{\text{II}}}{2} \quad \text{.................................(22)}$$

Substitution of the previously defined dimensionless variables and Eq. 22 into Eq. 21 and rearranging, yields the following dimensionless
\[ (F + y_1^*) (c_1 y_1^* - 2c_2 y_1^* + c_2 y_1^* + 2) 10/3 + G_1 (c_1 y_1^* - 2c_2 y_1^* + c_2 y_1^* + 2)^{4/3} \\
- G_2 (c_1 - 2c_2 + c_3 y_1^*)^{4/3} = 0 \] .................................. (23)

in which
\[ F = \frac{S_o L}{N \eta} - y_{II}^* - \frac{G_1}{(c_1 y_{II}^* - 2c_2 y_{II}^* + c_2 y_{II}^* + 2)^2} \]
\[ = \frac{G_2 (c_1 - 2c_2 + c_3 y_{II}^*)^{4/3}}{(c_1 y_{II}^* - 2c_2 y_{II}^* + c_2 y_{II}^* + 2)^{10/3}} \] .................................. (24)
\[ G_1 = \frac{Q_o^2}{2g \eta^3} \] .................................. (25)
\[ G_2 = \frac{\eta^2 L Q_o^2}{4.42 N \eta^{13/3}} \] .................................. (26)

and \( N \) is the number of \( \delta x \) reaches along the reservoir, i.e.
\[ N = \frac{L}{\delta x} \] .................................. (27)

If \( y_{II}^* \) is known, Eq. 23, has only one unknown variable, \( y_1^* \), which may be determined by Newton's Iteration Technique (10, 11).

The Newton Technique is an iterative method for solving a nonlinear equation of the form, \( f(x^*) = 0 \), by generating a sequence of successive approximations which, if a proper initial value of \( x^* \) is used, converges to a desired root of the equation. The recurrence formula is
\[ x_{k+1}^* = x_k^* - \frac{f(x_k^*)}{f'(x_k^*)} \] .................................. (28)

in which \( f'(x_k^*) = \frac{df}{dx}_{x_k^*} \) and the \( k \) and \( k+1 \) subscripts indicate the \( k^{th} \)
and \((k+1)^{th}\) approximate values of the desired root \((6)\).

The first \(\delta x\) reach, for which \(y^*_I\) is sought, is located immediately upstream of the downstream boundary, hence \(y^*_{II} = 1\). The first approximation for \(y^*_I\) is simply taken as \(y^*_{II}\). After \(y^*_I\) has been computed to within a prescribed error tolerance, \(v^*_I\) is computed from the following

\[
 v^*_I = \frac{(c_1 - c_2)}{(c_1 y^*_I - 2c_2 y^*_I + c_2 y^*_I)^2} \tag{29}
\]

Proceeding upstream from the downstream boundary, depths and velocities are computed for sections located at \(\delta x\) intervals along the reservoir, by replacing the value of \(y^*_{II}\) in Eq. 23 with the recently computed \(y^*_I\) and repeating the above procedure. This process is repeated until all desired values of \(y^*\) and \(v^*\) are determined. These become the initial conditions which are necessary to start the procedure for solving the St. Venant equations.

**Steady State Parameters.** - The following steady state dimensionless parameters are used to monitor the type of flow regime at the upstream boundary

\[
y^*_n = \frac{y_n}{\eta} \quad y^*_c = \frac{y_c}{\eta} \quad y^*_s = \frac{y_s}{\eta} \tag{30}
\]

where \(y_n\) is the normal depth, \(y_c\) the critical depth, and \(y_s\) the sequent depth of the normal depth \(y_n\), all for a steady flow of \(Q_o\).

The normal depth \(y^*_n\) is obtained by applying Manning's equation to the flow at a section. Thus,

\[
 \frac{Q_o}{1.49S_o^{1/2}} \left[ c_1 y^*_n - 2c_2 y^*_n \right]^{2/3} - \left[ c_1 y^*_n - 2c_2 y^*_n + c_2 y^*_n \right]^{5/3} = 0
\]

\[
 \text{(31)}
\]
which is solved for \( y^*_n \) by Newton's technique where the first approximation for \( y^*_n \) is determined by tacitly assuming the reservoir is a wide channel. Thus,

\[
y^*_n = \left[ \frac{Q_o}{1.49S_o^{1/2}(c_1-c_2)} \right]^{3/5}/\eta \tag{32}
\]

Upon applying the principle of minimum energy (5) to a flow cross section, the following equation is developed

\[
\frac{Q_o}{g^{1/2}} \left( c_1-2c_2+c_2y^*_c \right)^{1/2} - [(c_1y^*_c-2c_2y^*_c+c_2y^*_c^2\eta)]^{3/2} = 0
\]

\[
\tag{33}
\]

where Eq. 33 is solved for \( y^*_c \) by Newton's technique with the first approximation for \( y^*_c \) taken as

\[
y^*_c = \left[ \frac{Q_o}{g^{1/2}(c_1-c_2)} \right]^{2/3}/\eta \tag{34}
\]

\( S_o \) is mild and the initial backwater curve is the M1 type if \( y^*_n > y^*_c \) \tag{35}

\( S_o \) is steep and the backwater curve is the S1 type if \( y^*_n < y^*_c \) \tag{36}

When the latter condition prevails, the upstream boundary is repositioned downstream such that the depth \( y^*_u \) exceeds the sequent depth, \( y^*_s \).

In this way, the flow in the portion of the reservoir, for which the St. Venant equations and boundary conditions are applied, is subcritical.

This procedure introduces negligible error into the simulation model,
since the sequent depth is quite small for all reservoir sizes and flowrates of practical interest. If it should be desired to simulate both the supercritical and subcritical flow upstream and downstream of the moving flow discontinuity (hydraulic jump) at the upper end of the reservoir, an explicit numerical technique known as the Lax method (11, 29, 30) can be used to solve the St. Venant equations when they are expressed in their "conservation form".

The sequent depth $y^*_s$ is determined by applying the momentum principle (5) to the discrete section of the reservoir at which a discontinuity occurs. Thus,

$$\frac{Q_o^2}{gn(c_1 y^*_s - 2c_2 y^*_s + c_2 y^*_n)} + \eta^2 y^*_s \left( \frac{c_1}{2} - c_2 + \frac{c_2 y^*_s}{3} \right) - K_s = 0$$

...(37)

where

$$K_s = \frac{Q_o^2}{gn(c_1 y^*_n - 2c_2 y^*_n + c_2 y^*_s)} + \eta^2 y^*_n \left( \frac{c_1}{2} - c_2 + \frac{c_2 y^*_n}{3} \right)$$

...(38)

Eq. 37 is solved for $y^*_s$ by Newton's technique with

$$y^*_s = \frac{y^*}{2} \left( \sqrt{1 + \frac{8Q^2}{g^3 n}} \right) - 1$$

...(39)

where

$$\frac{(c_1 - c_2)}{(c_1 y^*_n - 2c_2 y^*_n + c_2 y^*_s)}$$

...(40)

Numerical Solution of St. Venant Equations. - The St. Venant equations defy a closed-form solution; however, they may be solved by
numerical techniques such as the explicit method (3, 7, 11, 13, 14, 16, 18, 21, 22, 26, 27), the implicit method (1, 3, 7, 18) and the method of characteristics with a characteristic network (2, 3, 7, 9, 11, 17, 19, 28, 3) and a rectangular network (4, 8, 19, 23, 28, 33). Each of the techniques offer particular advantages and disadvantages (11, 18). The method of characteristics with a characteristic network is used herein because of its inherent numerical stability and the ease with which boundary conditions may be introduced into the solution procedure. Also, the prismatic geometry of the idealized reservoir and the desirability of obtaining solutions at only the upstream and downstream boundaries lend to the selection of the method of characteristics.

**Characteristic Equations.** - In the method of characteristics, the two St. Venant partial differential equations are converted into four ordinary differential equations, called "characteristic equations", which may be numerically integrated subject to specified boundary conditions. The conversion is accomplished by forming a linear combination of Eqs. 13 and 14 through the use of a multiplier, $\psi$ (4, 11, 19, 24, 27, 28). Thus,

$$\frac{\partial y^*}{\partial t} + K_1 v^* \frac{\partial v^*}{\partial x} + v^* \frac{\partial y^*}{\partial x} + \psi \frac{\partial v^*}{\partial t} + v^* \frac{\partial v^*}{\partial x} + K_2 \frac{\partial y^*}{\partial x} +$$

$$\frac{K_3 \gamma^* v^*}{R^* \gamma^*} - K_4 = 0 \quad \ldots \ldots \ldots \ldots \ldots \ldots \ldots (41)$$

Upon rearranging Eq. 41 such that partial derivatives of $y^*$ and $v^*$ are grouped separately, i.e.
\[ \psi \left[ \frac{\partial v^*}{\partial t} + (v^* + \frac{K_1D^*}{\psi}) \frac{\partial v^*}{\partial x^*} \right] + \left[ \frac{\partial y^*}{\partial t} + (v^* + \psi K_2) \frac{\partial y^*}{\partial x^*} \right] + \psi = 0 \]

\[ \frac{K_3}{R^{4/3}} |v^*|^v - K_4 = 0 \]  \hspace{1cm} (42)

The bracketed quantities may be made total derivatives, i.e. \( \frac{dv^*}{dt^*} \) and \( \frac{dy^*}{dt^*} \)

if \( v^* + \frac{K_1D^*}{\psi} = \frac{dx^*}{dt^*} \)  \hspace{1cm} (43)

and \( v^* + K_2\psi = \frac{dx^*}{dt^*} \)  \hspace{1cm} (44)

The simultaneous solution of Eqs. 43 and 44 yields \( \psi \). Thus,

\[ \psi = \pm \sqrt{\frac{K_1D^*}{K_2}} \]  \hspace{1cm} (45)

Substitution of Eq. 45 into Eqs. 42-44 and rearranging, yields

\[ \frac{dv^*}{dt^*} - \sqrt{\frac{K_2}{K_1D^*}} \frac{dy^*}{dt^*} + \frac{K_3}{R^{4/3}} \frac{|v^*|^v}{R^{4/3}} - K_4 = 0 \]  \hspace{1cm} (46)

\[ \frac{dx^*}{dt^*} = v^* - \sqrt{K_1K_2D^*} \]  \hspace{1cm} (47)

\[ \frac{dv^*}{dt^*} + \sqrt{\frac{K_2}{K_1D^*}} \frac{dy^*}{dt^*} + \frac{K_3}{R^{4/3}} \frac{|v^*|^v}{R^{4/3}} - K_4 = 0 \]  \hspace{1cm} (48)

\[ \frac{dx^*}{dt^*} = v^* + \sqrt{K_1K_2D^*} \]  \hspace{1cm} (49)
Eqs. 46 and 47 are associated with the C- characteristic curves in the $x^*-t^*$ solution plane, shown in Fig. 4; Eqs. 48 and 49 are associated with the C+ characteristic curves. It is noted that Eqs. 46 and 48 contain no partial derivatives; however, the additional Eqs. 47 and 49 are required since Eqs. 46 and 48 are valid only along the curves defined by the $dx^*/dt^*$ expressions. All four equations are valid at intersection points, such as p, in the $x^*-t^*$ plane. Thus, if the values of $x^*, t^*, y^*$, and $v^*$ are known at points, l and r, a numerical integration of the equations will produce the values of $x^*, t^*, y^*$, and $v^*$ at point p. In this way, the values associated with all intersection points in the $x^*-t^*$ plane are determined sequentially from left to right while progressing upward in the $t^*$-direction.

The numerical integration of Eqs. 46-49 may be accomplished by various finite-difference approximations with different orders of accuracy (2,3,11,19,29). It was found that a simple first-order approximation of the form

$$\int_{x^*}^{x^*} f(x^*)dx^* \approx f(x^*_r)(x^*_p-x^*_r) \tag{50}$$

provided sufficient accuracy since the variation of $v^*$ and $y^*$ with $x^*$ and $t^*$ is relatively small for a flow produced by a gradual breach.

Upon applying Eq. 50 to Eqs. 46-49 and rearranging, four equations, which are linear with respect to the variables at location p, are obtained as follows
FIGURE 4. $x^*-t^*$ PLANE WITH CHARACTERISTIC NETWORK
\[ v_p^*-v_r^*-F_2(y_p^*-y_r^*)+F_3(t_p^*-t_r^*)=0 \] ..............................(51)

\[ x_p^*-x_r^* = F_4(t_p^*-t_r^*) \] ..............................(52)

\[ v_p^*+v_1^*+F_5(y_p^*-y_1^*)+F_6(t_p^*-t_1^*)=0 \] ..............................(53)

\[ x_p^*-x_1^* = F_4(t_p^*-t_1^*) \] ..............................(54)

**where**

\[ F_1 = \sqrt{\frac{v_p^*-\sqrt{K_1 K_2 D_r^*}}{r}} \] ..............................(55)

\[ F_2 = \sqrt{\frac{K_2}{K_1 D_r^*}} \] ..............................(56)

\[ F_3 = \frac{K_3 v_r^* \left| v_r^* \right|}{R_r^* 4/3} - K_4 \] ..............................(57)

\[ F_4 = v_1^* + \sqrt{\frac{K_1 K_2 D_1^*}{1}} \] ..............................(58)

\[ F_5 = \sqrt{\frac{K_2}{K_1 D_1^*}} \] ..............................(59)

\[ F_6 = \frac{K_3 v_1^* \left| v_1^* \right|}{R_1^* 4/3} - k_4 \] ..............................(60)

Substitution of \( y_1^* \) and \( y_r^* \) for \( y^* \) in Eq. 10 and 11, provides the values of \( D_1^*, D_r^*, R_1^*, R_r^* \).

**Upstream Boundary.** - The V-breach is assumed to occur during a short duration of time relative to the time base of the reservoir inflow hydrograph. The inflow occurs only at the upper reach of the idealized reservoir such that the reservoir is not subjected to any lateral inflow. Hence, the inflow to the reservoir may be considered
relatively constant throughout the formation of the breach, and the upstream boundary condition is expressed as a constant inflow, i.e.

\[ Q_u = Q_u(t) = Q_o \] (61)

and in dimensionless form,

\[ Q_u^* = \frac{Q_u}{Q_o} = 1 \] (62)

Thus, from continuity considerations

\[ v_u^* = \frac{Q_u^*(c_1-c_2)}{(c_1y_u^*-2c_2y_u^*+c_2y_u^*2)} \] (63)

The value of \( x_u^* \) is known since it represents the location of the upstream boundary; hence, \( t_u^* \) may be computed from the C-Eq. 52,

\[ t_u^* = t_u^* + \frac{(x_u^*-x_u^*)}{r} \] (64)

Substitution of Eq. 63 into the C-Eq. 51 yields

\[ (F_u - F_2y_u^*)(c_1y_u^*-2c_2y_u^*+c_2y_u^*2)+Q_u^*(c_1-c_2)=0 \] (65)

where

\[ F_u = -v_u^* + F_2y_u^* + F_3(t_u^*-t_u^*) \] (66)

Eq. 65 may be solved for \( y_u^* \) by Newton's technique with

\[ y_u^* = y_u^* \] (67)

where the \( u_o \) subscript is associated with the previously computed upstream boundary point shown in Fig. 4. The value for \( v_u^* \) is computed from Eq. 63.
**Interior Points.** - The unknown values of $x^*, t^*, y^*$ and $v^*$ at any interior point designated by a $p$ subscript may be easily obtained from the simultaneous solution of the four linear Eqs. 51-54.

Thus,

$$t_p^* = \frac{(x_1^* - x_r^* + F_1 t_r^* - F_4 t_{1p}^*)}{(F_1 - F_4)} \quad (68)$$

$$x_p^* = x_1^* + F_4 (t_p^* - t_r^*) \quad (69)$$

$$y_p^* = \frac{[v_1^* - v_{1r}^* + F_2 y_r^* + F_5 y_1^* + F_3 (t_p^* - t_r^*) - F_6 (t_{1p}^* - t_{1r}^*)]}{(F_2 + F_5)} \quad (70)$$

$$v_p^* = v_1^* - F_5 (y_{1p}^* - y_{1r}^*) - F_6 (t_{1p}^* - t_{1r}^*) \quad (71)$$

**Downstream Boundary.** - The location of the downstream boundary is known; hence,

$$x_d^* = 1 \quad \ldots \quad (72)$$

and $t_d^*$ may be computed from the C+ Eq. 54, i.e.

$$t_d^* = t_r^* + \frac{(x_d^* - x_r^*)}{F_4} \quad \ldots \quad (73)$$

The downstream boundary condition is given by stage-discharge relationships for the spillway and the V-breach. The elevation of the spillway crest $\eta_{sp}^*$ is constant, however, the elevation of the bottom of the V-breach $\eta_v^*$ is a function of $t_d^*$, $\eta_{lt}^*$, $\eta_{lb}^*$, and $\lambda^*$. The following step-functions express this variation of $\eta_v^*$.

If $$\eta_{vo}^* > \eta_{lt}^* \quad \ldots \quad (74)$$

then $$\eta_v^* = \eta_{vo}^* - \lambda^* (t_d^* - t_{do}^*) \quad \ldots \quad (75)$$
however if $\eta_v^* < \eta_{lt}^*$ ...........................................(76)
then
$\eta_v^* = \eta_{lt}^* - \frac{[\lambda \tau^*_d -(\eta_{vo}^* - \eta_{lt}^*)]}{K_\lambda^*}$. .................(77)

If $\eta_{lb}^* < \eta_{vo}^* < \eta_{lt}^*$ ...........................................(78)
then
$\eta_v^* = \eta_{vo}^* - \frac{\lambda^*}{K_\lambda^*} (t^*_d - t^*_{do})$. ...............(79)

however if $\eta_v^* < \eta_{lb}^*$ ...........................................(80)
then
$\eta_v^* = \eta_{lb}^* - [\lambda \tau^*_d - K_\lambda^* (\eta_{vo}^* - \eta_{lb}^*)]$. .................(81)

If $0 < \eta_{vo}^* < \eta_{lb}^*$ ...........................................(82)
then
$\eta_v^* = \eta_{vo}^* - \lambda^* (t^*_d - t^*_{do})$. .........................(83)

however if $\eta_v^* < 0$ ...............................................(84)
then
$\eta_v^* = 0$. ......................................................(85)

The second subscript, o, indicates that the subscripted variable is the previously computed boundary point as shown in Fig. 4.

The velocity at the downstream boundary is expressed in terms of the discharges of the spillway and the V-breach, and the reservoir cross-section, i.e.

$$v_d^* = \frac{[K_5(y_d^* - n_v^*)^{5/2} + K'_K_6(y_d^* - n_{sp}^*)^{3/2}](c_1 - c_2)}{(c_1 y_d^* - 2 c_2 y_d^* + c_2 y_d^* d^2)}$$. ...........(86)

where, $K' = 1$ ......................................................(87)
\[ y_d^* > \eta_{sp}^* \] ............................................... (88)

and
\[ \kappa' = 0 \] ............................................... (89)

if
\[ y_d^* < \eta_{sp}^* \] ............................................... (90)

and
\[ K_5 = C_v \eta^{5/2}/Q_o \] ............................................... (91)
\[ K_6 = C_{sp} \eta^{3/2}/Q_o \] ............................................... (92)
\[ C_v = 4.28 c_v \tan \frac{\phi}{2} \] ............................................... (93)
\[ C_{sp} = 5.36 c_{sp} L_{sp} = Q_o/[\eta(1-\eta_{sp}^*)]^{3/2} \] ............................................... (94)

Substitution of Eq. 86 into the C+ Eq. 53 yields
\[
K_5(y_d^* - \eta_{sp}^*)^{5/2} + K_6(y_d^* - \eta_{sp}^*)^{3/2} + \frac{(c_1 y_d^* - 2 c_2 y_d^* + c_2 y_d^* \overline{y}_d^*)}{(c_1 - c_2)} (F_4 y_d^* + F_d)
\]
\[ = 0 \] ............................................... (95)

where
\[ F_d = -v_{1}^* - F_{5} y_{1}^* + F_{6} (\tau_{d}^* - \tau_{1}^*) \] ............................................... (96)

Eq. 95 may be solved for \( y_d^* \) by Newton's technique with
\[ y^*_{d_l} = y_d^* \] ............................................... (97)

Then, \( v_d^* \) is computed from Eq. 86 and the reservoir release discharge \( Q_d^* \) is computed from the following
\[ Q_d^* = \frac{v_d^*(c_1 y_d^* - 2 c_2 y_d^* + c_2 y_d^* \overline{y}_d^*)}{(c_1 - c_2)} \] ............................................... (98)
Optimization of Retarding Layer Location. - When a dam does not have an erosion retarding layer, the maximum possible reservoir release \( Q_{dmp}^* \) due to a breached dam occurs at \( \eta_{vmp}^* \) which may be at any elevation within the dam; this elevation depends upon the magnitude of the reservoir surface area, bottom slope, the failure rate \( \lambda \) and \( C_v \). When \( Q_{dmp}^* \) occurs, the two factors controlling the rate of discharge through the breach, namely the head \( y_d^* - \eta_v^* \) on the breach and the flow area of the breach must assume their maximum simultaneous values. Thereafter and until practically all of the storage above \( y_n^* \) is released, the reservoir surface level \( y_d \) decreases since the reservoir outflow \( Q_d^* \) exceeds the reservoir inflow \( Q_u \).

The optimum elevation \( \eta_{1t0p}^* \) of the retarding layer is defined herein as that elevation which minimizes the maximum reservoir outflow \( Q_{dm}^* \). Thus, by optimally positioning the retarding layer, a maximum reduction in \( Q_{dmp}^* \) is achieved. Such a reduction, denoted as QR, is defined as a percentage reduction, i.e.

\[
QR = \frac{(Q_{dmp}^* - Q_{dm}^*)}{Q_{dmp}^*} \times 100 \quad \text{(99)}
\]

An iterative procedure is utilized to determine \( \eta_{1t0p}^* \) within an acceptable accuracy. Initially, the breach is simulated with \( \eta_{1t}^* \) equal to zero, i.e. the dam does not have a retarding layer; and \( Q_{dmp}^* \) is determined. Then, the breach is simulated with the retarding layer positioned at \( \eta_{1t_k+1}^* \) which is defined as

\[
\eta_{1t_k+1}^* = \eta_{1t_k}^* + \delta \eta_{1t}^* \quad \text{(100)}
\]
where the subscript denotes the number of iterations using an incremental increase of $\delta \eta_{lt}^*$ and $\eta_{lt_1}^* = \eta_{vmp}^*$. The simulation of the breach, with the retarding layer positioned at $\eta_{lt_{k+1}}^*$, is continued until $\eta_v^* < \eta_{vmp}^*$ since all subsequent $Q_d^*$ must be less than that occurring when $\eta_v^*$ has reached $\eta_{vmp}^*$. When the dam has a retarding layer that is positioned above the $\eta_v^*$ at which $Q_{dmp}^*$ occurred, $Q_{dm}^*$ will be less than $Q_{dmp}^*$ since the retarding layer allows the water level in the reservoir to recede while the area of the breach remains relatively constant. Thus, $Q_{dm}^*$ will occur at some $\eta_v^*$ which is greater than $\eta_{vmp}^*$.

The reduction in $Q_{dmp}^*$, denoted as $QR^*$, is a function of the position $\eta_{lt}^*$ of the retarding layer. A typical relationship between $QR^*$ and $\eta_{lt}^*$ is shown in Fig. 5. The function, $QR = QR(\eta_{lt}^*)$, was investigated for a variety of reservoir parameters ($L$, $\eta$, $Q_0$, $\lambda$, etc.) and was found to contain only one maximum value. Thus, the difficulties encountered when a function contains more than one maximum (peak) is avoided in the iterative search for $\eta_{lt_0p}^*$.

Using an incremental increase $\delta \eta_{lt}^*$, $QR_k^*$ is computed for each position of the retarding layer until $QR_{k+1}^*$ is greater than $QR_k^*$. When this occurs, as noted in Fig. 5, $QR_{max}^*$ and the corresponding $\eta_{lt_0p}^*$ exists for a value of $\eta_{lt}^*$ less than $\eta_{lt_{k+1}}^*$. Then $QR_{k+2}^*$ and $QR_{k+3}^*$ are computed, and the final location of $QR_{max}^*$ is easily obtained graphically by extending smooth curves through all the computed points $(QR, \eta_{lt_k}^*)$.

**Modifications to Model.** - Modifications may readily be made to the above numerical simulation model to accommodate reservoir geometries,
FIGURE 5. TYPICAL VARIATION OF THE PERCENT REDUCTION (QR) IN THE MAXIMUM POSSIBLE RESERVOIR RELEASE WITH THE LOCATION \( (\eta^*_{lt}) \) OF THE EROSION RETARDING LAYER
bottom slopes, breach geometries, upstream and downstream boundary conditions, and breach dynamics which differ from those treated herein.

Rectangular or triangular reservoir cross sections may be simulated by letting $z=0$ or $z=L/(2\tau \eta_\text{r})$, respectively. Other cross-sectional geometries may be handled by properly defining $A$, $D$, and $R$. The reservoir bottom slope $S_0$ may be defined other than by Eq. 4 and thus be independent of $\eta$ and $L$. Breach geometries, other than a V-shape may be simulated by defining the cross-sectional area of the breach as a function of $\eta_\text{v}^*$. A principal spillway and/or a different type of emergency spillway may be incorporated into the downstream boundary condition by defining their respective stage-discharge relationships and elevations. The discharge coefficients $C_{sp}$ and $C_v$ of the spillway and V-breached may be expressed as functions of $y_d^*$, $\eta_{sp}$, and or $\eta_v$ rather than assumed to be constants.

The upstream boundary condition may be changed to a stage or discharge hydrograph by specifying the relationship between the upstream stage or discharge with time.

The initiation of the breach may be defined so as to occur when the depth $y_d^*$ at the downstream boundary exceeds $\eta_\text{r}^*$ by a specified amount. The failure rate $\lambda$ may be described by various mathematical functions other than Eqs. 5 and 6.

EXPERIMENTAL SIMULATION MODEL

An experimental simulation model was developed to check the accuracy of the numerical model. A vertical dam, consisting of two adjacent,
metal plates, was installed near the midpoint of a 40 ft. long by 2 ft. wide Plexiglas flume. The thin metal plates were shaped such that a V-opening was formed at the centerline of the dam when the plates were moved in opposite horizontal directions parallel to the flume cross section. The $\phi$ angle of the V-opening (breach) remained constant throughout its formation and gradual enlargement. A magnetic clutch provided an instantaneous application of a variable speed drive-unit to a cable-pulley system which pulled the metal plates apart. This system permitted the V-breath to be formed at any desired rate $\lambda$ from 0.0 - 0.15 fps.

The simulated reservoir formed by the two-dimensional metal dam was of rectangular cross section having a depth $y_d$ of 1.704 ft. at the dam. A steady inflow $Q_o$ was introduced at the upstream end of the reservoir and the same quantity was released from the reservoir through a small V-opening at the top of the dam. This outflow simulated the steady spillway discharge assumed to occur prior to an over-topping failure. The V-opening was enlarged at a known rate $\lambda$; this simulated the formation of a gradual V-shaped breach. A timed-pause in the formation of the V-breath simulated the effect of an erosion retarding layer.

The discharge coefficient $C_v$ of the V-breath was determined for numerous steady flows at various settings of the metal plates so as to provide steady state discharge coefficients which spanned the entire range of possible V-openings ($\eta_v$) and heads ($y_d - \eta_v$) on the V-breach. The discharge coefficient was found to vary with both $\eta_v$ and $y_d$. This variation was expressed in the form

$$C_v = K_{c1} \left( \frac{y_d - \eta_v}{\eta_v} \right)^{-K_2} \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots
where $K_{c1}$ varied from 1.580 to 1.634 and $K_{c2}$ varied from 0.001 to 0.098; both are functions of $(y_d - n_v)$ and $n_v$.

Timers and staff gauges, positioned at stations 1.00 and 10.00 ft. upstream from the dam, were continuously monitored via movie cameras. This provided stage hydrographs at the selected stations. Total outflow $Q_t$ from the reservoir was determined for a specified duration of time $t_f$ after the time $t_o$ at which movement of the metal plates was initiated. Thus,

$$Q_t = Q_{o}t_f + TL(y_{d_t_o} - y_{d_t_f})$$

(102)

**NUMERICAL RESULTS**

**Comparison With Experimental Results.** - The numerical simulation model provides results which are in satisfactory agreement with the experimental model. A typical stage hydrograph for station 1.00 is shown in Fig. 6 along with the stage as computed by the numerical model. The percent standard deviation $C_{y_d}$ between the experimental and numerical $y_d$ is 1.17%, and for all experimental runs, $C_{y_d}$ is 0.83%. The computed outlet discharge hydrograph associated with the stage hydrograph is also shown in Fig. 6. Total outflow, as computed by the numerical model, is determined by numerically integrating the discharge hydrograph. The percent standard deviation $C_{Q_t}$ between the experimental and numerical total outflows is 5.1% for all experimental runs. Additional experimental-numerical stage and discharge hydrographs for this study are presented in reference (12).

**FIGURE 6.**
Retarding Layer: Optimal Location and Reduction in Outflow. Upon applying the numerical simulation model to a range of reservoir sizes, dam heights, initial flowrates, and dam failure rates, prediction curves are obtained for the dimensionless optimal elevation $\eta^{*}_{ltop}$ of the erosion retarding layer and the extent of its reduction $QR_{max}$ in the reservoir outflow. The results are functions of the parameters used herein to describe the transient hydraulics associated with the gradual V-breach of an earthfill dam. These parameters consist of the following: geometric parameters ($L$, $K_{la}$, $\tau$, $\eta$, $n_{sp}$, and $n_{ld}$); hydraulic parameters ($Q_0$, $n$, $C_v$); and dynamic parameters ($\lambda$ and $K_{la}$).

The values of $\eta^{*}_{ltop}$ and $QR_{max}$ are expressed as functions of the dimensionless failure rate $\lambda^*$, as defined by Eq. 19, and for specific values of $L$, $\tau$, $\lambda^*_c$, $\eta$, and $K_{la}$. The prediction curves for $\eta^{*}_{ltop}$ and $QR_{max}$ are applicable for the "fixed parameters", $K_{la}=1.2$, $z=2$, $n_{sp}=0.95$, $n_{ld}=0.02$, $n=0.03$ and $C_v=2.2$. The sensitivity of the prediction curves to variations in these fixed parameters is examined in a following section.

Prediction curves for $\eta^{*}_{ltop}$ and $QR_{max}$ are shown in Figures 7-12 for specific values of $L$, $\tau$, $K_{la}$ and $\lambda^*_c$. The following example illustrates the use of the prediction curves:

When $Q_0=2,000$ cfs, $L=10,000$ ft, $\tau=10$, $n=100$ ft, $\lambda^*_c=0.01$ fps, $K_{la}=100$, $K_{la}^*=1.2$, $z=2$, $\eta^{*}_{sp}=0.95$, $\eta^{*}_{ld}=0.02$, $n=0.03$, and $C_v=2.2$, the optimum elevation $\eta^{*}_{ltop}$ of an erosion retarding layer and the corresponding reduction $QR_{max}$ in the maximum possible reservoir release may be obtained from Fig. 8. First, $\lambda^*$ is computed from Eq. 19, i.e. $\lambda^* = \frac{(10000)(.01)}{2000}$

$\frac{10000}{10} - 2(100) = 40$. Then a line is extended vertically from

FIGURE 12. RELATIONSHIP BETWEEN $QR_{\text{max}}$ AND $\eta^*_{t\text{op}}$ FOR VARIOUS VALUES OF $\lambda^*$ AND $L=2,000$ ft., $\tau=4$, $\lambda_c=0.005$ fps
Figure 12.
the abscissa at $\lambda^* = 40$ to intersect the curves pertaining to $K_\lambda = 100$ and $\eta = 100$ ft. as shown in Fig. 8. Finally, the values of $\eta^*_{1t0p}$ and $QR^*_{\text{max}}$ are obtained by extending lines horizontally until they intersect the appropriate ordinate axis, and $\eta^*_{1t0p}$ and $QR^*_{\text{max}}$ are read as 0.463 and 45.8%, respectively.

Upon examining Figs. 7-12, it is evident that $\eta^*_{1t0p}$ significantly varies directly with $\eta$ and $K_\lambda$ and inversely with $L$ and $\lambda^*_c$. Also, in all except Fig. 7, $\eta^*_{1t0p}$ varies directly with $\lambda^*$.

If the failure rate $\lambda^*_c$ is very small and/or $L$ is small, say $L = 2000$ ft., the reservoir depth as determined by the numerical model recedes at an increasing rate as the V-breach forms. Under this condition, the maximum possible reservoir release $Q^*_{\text{dmp}}$ occurs when the rate at which the depth is receding exceeds the failure rate $\lambda^*_c$, i.e. $Q^*_{\text{dmp}}$ occurs considerably before the breach achieves its maximum size. Hence, $\eta^*_{1t0p}$ may assume values in the range of 0.60 to 0.75. Under this same condition of small values of $\lambda^*_c$ and/or $L$, the elevation of the erosion retarding layer is critical since it is possible for the layer, if incorrectly positioned above $\eta^*_{\text{vmp}}$, to cause $Q^*_{\text{dm}}$ to exceed $Q^*_{\text{dmp}}$.

In Figs. 7-12, $QR^*_{\text{max}}$ assumes values in the range of 10 to 65%. This indicates that significant reductions in the maximum reservoir release from gradually breached dams may be achieved by the presence of an erosion retarding layer which is optimally located. The extent of the reduction $QR^*_{\text{max}}$ is primarily related directly to the resistance of the layer to erosion, i.e. $K_\lambda$, and to $\lambda^*$.

Prediction curves for $\eta^*_{1t0p}$ and $QR^*_{\text{max}}$ are shown in Figs. 13 and 14 for specific values of $L$, $r$, $\eta$, $K_\lambda$, $\lambda^*_m$, and $y^*_{\text{dm}}$. In these, $\lambda$ is

FIGURE 14.
assumed to be an exponential failure rate as described by Eq. 7. The prediction curves in Figs. 13 and 14 are similar to those in Figs. 7 and 8, respectively. The exponential failure rate produces values of $\eta_{1t0p}$ and $QR_{\text{max}}$ which are approximately 10% greater than those computed for a constant failure rate. In Figs. 13 and 14, $QR_{\text{max}}$ assumes values in the range of 10 to 75%.

**Sensitivity to Variations in Fixed Parameters.** - The sensitivity of the $\eta_{1t0p}$ and $QR_{\text{max}}$ values, as presented in Fig. 8, to variations in the values of the "fixed parameters" is shown in Table 1. The variations in the values of the fixed parameters span the practical range of each. The sensitivity is determined as an average percentage change in the values of $\eta_{1t0p}$ and $QR_{\text{max}}$ as determined with the fixed parameters having the values designated in the preceding section.

Variations in $C_v$, $\eta_{sp}$, $z$ and $n$ result in changes of about 10% or less in $\eta_{1t0p}$ and $QR_{\text{max}}$. Variations in $\tau$ and $C_v$ produce more significant changes in $\eta_{1t0p}$ of approximately 12 to 30%. Also, as noted in Table 1, variations in $\tau$ and $C_v$ produce changes in $QR_{\text{max}}$ of approximately 15 to 38%. Variations in $\eta_{1d}$ result in significant changes in $\eta_{1t0p}$ and $QR_{\text{max}}$ when $K_\lambda = 100$ and $\eta = 50$ ft; however, the changes are not significant when $K_\lambda = 500$ and $\eta = 50$ or 100 ft.

**Computation Time.** - The maximum computation time $C_t$ in seconds, which is required for the numerical model to determine the transient hydraulics, for a particular set of geometric, hydraulic and dynamic parameters, may be approximated by the following

</table>
\[ C_t \approx C_p + K_{op} C_{kt} \] ...........................(103)

where

\[ T = \frac{N}{2L \lambda_c} \left[ \frac{Q_o}{\eta(c_1-c_2)} + \sqrt{\frac{g \eta(c_1-c_2)}{c_1}} \right] [\eta + \eta_{ld}(K_{\lambda}-1)] \] ...........................(104)

and \( C_p \) is the constant compile time, \( K_{op} \) is a multiplier which reflects the additional computation time required when the retarding layer optimization procedure is utilized, and \( C_{kt} \) is a constant. When the computations are performed on an IBM/360 computer, \( C_p = 94 \) seconds and \( C_{kt} = 0.020 \) seconds. If the retarding layer elevation is not optimized, \( K_{op} = 1; \) otherwise, \( K_{op} \) varies from 4 to 10 depending upon the magnitude of \( (\eta_{lto} - \eta_{vmp}) \).

**SUMMARY AND CONCLUSIONS**

A conceptual method to reduce flood wave peaks due to over-topping failures of small homogeneous earthfill dams has been introduced. A numerical simulation model based upon a characteristic numerical solution of the St. Venant unsteady flow equations is presented for predicting the transient reservoir flow produced by the gradual breach of an earthfill dam.

The extent of reduction in the reservoir outflow from a breached dam due to the presence of a hypothetical erosion retarding layer is presented, along with the optimal elevation of the retarding layer, for a wide range of pertinent geometric, hydraulic, and dynamic parameters. The extent of reduction \( \text{QR}_{\text{max}} \) in the maximum outflow is primarily related directly to the ratio of the failure rate of the earthfill dam to the failure rate of the erosion retarding layer, i.e. \( K_\lambda \), and to the dimensionless failure rate \( \lambda^* \) which is defined by Eq. 19. This
reduction can be as significant as 75%. The dimensionless optimal
elevation \( \eta_{*lt0p} \), which minimizes the maximum reservoir outflow due
to the breach, is related directly to the height \( \eta \) of the dam, \( K_\lambda \),
and \( \lambda^* \) and inversely to the length \( L \) of the prismatic reservoir and to
the failure rate \( \lambda \). The exponential failure rate produces values of
\( \eta_{*lt0p} \) and \( QR_{max} \) which are approximately 10% greater than those computed
when the failure rate is constant.

Some sensitivity tests of the numerical model indicate that variations in the ratio of the width to the length of the prismatic reservoir,
i.e. \( \tau \), and the coefficient of discharge \( C_v \) of the V-breach significant-
ly affect the extent of reduction in outflow achieved by a retarding
layer, as well as, its optimal elevation. Variations in the dimension-
less thickness \( \eta_{*ld} \) of the retarding layer produce some significant
changes in \( \eta_{*lt0p} \) and \( QR_{max} \) as \( \eta \) and \( K_\lambda \) assume smaller values. However,
variations in the ratio of the total length \( L' \) of the reservoir to the
length \( L \) of the prismatic portion of the reservoir, i.e. \( K_1 \), the di-
mensionless elevation \( \eta_{*sp} \) of the spillway crest, the side slope \( z \) of
the trapezoidal reservoir cross section, and the Manning roughness
coefficient \( n \) produce relatively small changes in \( \eta_{*lt0p} \) and \( QR_{max} \).

When the prismatic reservoir length is small, say \( L=2000 \) ft., the
reservoir storage is depleted at a significantly increasing rate as
the breach forms. Hence, for failure rates of 0.01 fps and smaller, the
reservoir-water surface may eventually recede at a rate which is faster
than that at which the breach forms. Thus, the elevation of the tip of
the V-breach may be in the vicinity of \( \eta/2 \) when the maximum outflow is
attained. The optimal elevation of the retarding layer is located
above this; and its location is critical since an incorrect positioning can cause the outflow to exceed the maximum that would occur when no erosion retarding layer is present. When this condition exists and \( \eta = 100 \) ft., the reduction in the maximum outflow is relatively small as compared to that achieved by a retarding layer in an earthfill dam of a reservoir with a larger surface area.

The numerical model, as presented herein, may be used in its present form or modified, as required, to investigate the transient hydraulics of prismatic reservoirs subjected to unsteady flow introduced at either or both extremities of the reservoir.

ACKNOWLEDGEMENTS

The work upon which this paper is based and was supported in part by funds provided under Project No. A-0-35-MO of the United States Department of the Interior, Office of Water Resources Research, as authorized under the Water Resources Act of 1964, Dr. T. E. Harbaugh principal project investigator.

The writer would like to express special appreciation to Dr. T. E. Harbaugh of the Civil Engineering faculty, University of Missouri-Rolla for his advice concerning the research reported herein and for his extensive review of the paper.

\( x^* = \text{Unknown variable in Newton Iteration Technique} \)

\( y = \text{Depth of flow in channel (reservoir)} \)

\( y_c = \text{Critical depth for steady flowrate } Q_o \)

\( y_d = \text{Depth of flow at downstream boundary} \)

\( y_n = \text{Normal depth for steady flowrate } Q_o \)

\( y_s = \text{Sequent depth of } y_n \)

\( z = \text{Side slope of reservoir cross section} \)

\( \delta = \text{Very small increment} \)

\( \delta x = \text{Increment of channel (reservoir) length} \)

\( \delta \eta^*_{lt} = \text{Incremental increase in } \eta^*_{lt} \)

\( \eta = \text{Elevation of top of dam, with datum line at bottom of dam} \)

\( \eta_{lb} = \text{Elevation of bottom of erosion retarding layer} \)

\( \eta_{ld} = \text{Thickness of erosion retarding layer} \)
\( \eta_{lt} \) = Elevation of top of erosion retarding layer

\( \eta_{lt0p} \) = Optimal elevation of top of erosion retarding layer

\( \eta_{sp} \) = Elevation of emergency spillway crest

\( \eta_{v} \) = Elevation of bottom of V-breach when \( t=t_d \)

\( \eta_{vo} \) = Elevation of bottom of V-breach when \( t=t_{do} \)

\( \theta \) = Angle of inclination of channel bottom with the horizontal

\( \lambda \) = Failure rate of dam (rate of formation of the V-breach)

\( \lambda_c \) = Constant failure rate during a specified period of time or interval of elevation, \( \eta_v \)

\( \lambda_m \) = Estimated maximum failure rate when \( \eta_v = \eta_{vmp} \)

\( \sigma_{yd} \) = Percentage standard deviation of \( y_d \)

\( \sigma_{Qt} \) = Percentage standard deviation of \( Q_t \)

\( T \) = Parameter used in evaluating \( C_t \) and defined by Eq. 104

\( \tau \) = Ratio of initial top width \( T \) to reservoir length \( L \)

\( \phi \) = Acute central angle of V-breach

\( \psi \) = Linear multiplier

* = Superscript denoting a dimensionless variable
VITA

Danny Lee Fread was born on July 17, 1938, in Tuscola, Illinois. He received his primary and secondary education in Lovington, Illinois. He received his college education from Carthage College, Kenosha, Wisconsin and the Missouri School of Mines and Metallurgy, Rolla, Missouri. In May 1961, he received a Bachelor of Science degree in Civil Engineering from the Missouri School of Mines and Metallurgy, Rolla, Missouri.

In June 1961, he accepted a position with Texaco Inc. as an Assistant Design Engineer at the Lawrenceville refinery and remained with that firm until September 1967. During this period, he was advanced to the position of Senior Design Engineer and was registered as a Professional Engineer in the State of Illinois.

He enrolled in the Graduate School of the University of Missouri-Rolla in September 1967. He was the recipient of a National Defense Education Act Fellowship for the period of September 1967 to September 1970. He received a Master of Science degree in Civil Engineering from the University of Missouri-Rolla in May 1969. Since September 1970, he has served as co-investigator on a research project supported by the United States Department of Interior, Office of Water Resources Research. This project provided the information upon which this dissertation is based.
